# Pulse dynamics for reaction-diffusion systems in the neighborhood of codimension two singularity

Shin-Ichiro Ei, Yasumasa Nishiura and Kei-Ichi Ueda

Received on August 18, 2009

**Abstract.** The dynamics of a pulse for reaction-diffusion systems in 1D is considered in the neighborhood of the bifurcation point with codimension two, at which both of saddle-node and drift bifurcations occur at the same time. It is theoretically shown that when the bifurcation parameter is close to such a bifurcation point, a pulse moves with oscillation, and then starts to split.

*Keywords.* traveling pulse, self-replicating of pulses, saddle-node bifurcation, drift bifurcation

## 1. INTRODUCTION

In nature, many kinds of spatial and/or temporal patterns are observed in a variety of forms. To understand the dynamics of such patterns, mathematical modeling is one of the powerful approaches and a various types of models have been proposed and analyzed. Among them, reaction-diffusion systems are the most well-studied and display rich dynamics.

Recently, several reaction-diffusion model equations have been known as examples exhibiting various complicated behaviors of spatially localized patterns; self-replicating behavior of pulses ([13], [4] and their references), reflection of pulses ([3]), the behavior of pulses like elastic objects (e.g. [7], [8], [15], [14]), behaviors on inhomogeneous media ([11], [12]). Through these works, it has been known well that the properties of singularities have an important role to understand those complicated behaviors. For example, self-replicating behavior of pulses occurs near saddle-node bifurcation point ([13], [4]) and reflection of pulses does near the drift bifurcation point ([3]). To understand such dynamics theoretically, we will construct invariant manifolds around pulses locally for unstable modes but globally for translation.

In this paper, we will consider the dynamics of pulses near the degenerate bifurcation point with properties both of saddle-node and drift bifurcations. In the case, the bifurcation point is a singularity with codimension two except translation as in the assumption 4) in Section 4. Also we can construct invariant manifolds around pulses and write down the explicit equations of ODE describing the motion of the pulses. Thus the approach allows us to reduce the PDE dynamics to finite dimensional one and analyze various motions of pulses globally in space. Note that similar ODEs near the same codimension 2 singularity were for-

mally derived in [12] to understand the dynamics in heterogeneous media.

The details of mathematically technical parts will be stated in [5]. In this paper, we mainly analyze the reduced ODE in the neighborhood of codimension two bifurcation point and show the occurrence of an oscillatory traveling pulse and self-replication of it. We will also show by numerics that this situation really occurs in the Gray-Scott model on  $\mathbf{R}^1$ .

## 2. PULSE DYNAMICS IN THE GRAY-SCOTT MODEL

We consider the following equations called the Gray-Scott model [6]

$$(2.1) \quad \begin{cases} u_t &= d_1 u_{xx} - uv^2 + A(1 - u), \\ v_t &= d_2 v_{xx} + uv^2 - (A + k)v, \end{cases} \quad -\infty < x < \infty.$$

All coefficients  $d_1$ ,  $d_2$  and  $A$ ,  $k$  in (2.1) are positive constants. It is known that (2.1) show various dynamics of pulses depending on the parameters. Specially, there exist stable stationary pulse solutions for some parameter regions with a profile as in Fig1 (e.g. [1]). We note that the stationary solution converges  $(1, 0)$  as  $|x| \rightarrow \infty$ , where  $(1, 0)$  is a stable equilibrium of the kinetics of (2.1). When we fix the coefficients  $d_1$ ,  $d_2$  and  $A$  appropriately, the stable stationary pulse solutions exist for  $k \in (k_S, k_1)$  with  $0 < k_S < k_1$  and at  $k = k_S$ , there occurs a saddle-node type bifurcation, which has been numerically checked for many cases ([13]). The bifurcation structure causes the splitting dynamics for the parameter  $k = k_S - \varepsilon$  with sufficiently small  $\varepsilon > 0$  as in Fig 2 ([13], [4]).

On the other hand, for another pair of parameters  $(d_1, d_2, A)$ , there exist stable stationary pulse solutions for

Figure 1: Spatial profile of a stationary solution of (2.1).

Figure 2: Saddle-node type bifurcation and splitting dynamics.

$k \in (k_T, k_2)$  with  $0 < k_T < k_2$  and Jordan block type singularity appears at  $k = k_T$ . This has been also numerically checked ([13], [10], [3]). It is known that the singularity causes the bifurcation of traveling pulse solutions with pitch-fork type as in Fig 3 ([3]), which is called "drift bifurcation". In this paper, we assume the existence

Figure 3: One possibility of the bifurcation diagram of traveling pulses when Jordan block type singularity exists.

of the bifurcation structures both of saddle-node type and the Jordan block type in a general framework and show the splitting dynamics of an oscillating traveling pulse.

### 3. GENERAL FRAMEWORK AND RESULTS

In this section, we will give the several assumptions for the general settings.

Let us consider general type of reaction-diffusion systems with bifurcation parameters  $\mathbf{k}$  written by

$$(3.1) \quad \mathbf{u}_t = D\mathbf{u}_{xx} + F(\mathbf{u}; \mathbf{k}), \quad t > 0, \quad -\infty < x < \infty, \quad \mathbf{u} \in \mathbf{R}^N.$$

We assume  $\mathbf{k} \in \mathbf{R}^2$ .

Let  $\mathcal{L}(\mathbf{u}; \mathbf{k}) := D\mathbf{u}_{xx} + F(\mathbf{u}; \mathbf{k})$  and  $X := \{L^2(\mathbf{R}^1)\}^N$ . The assumptions are as follows:

1) There exist  $\mathbf{k} = \mathbf{k}_c$  and a stationary pulse solution  $S(x)$  of (3.1) such that  $\mathcal{L}(S(x); \mathbf{k}_c) \equiv 0$  and  $S(-x) = S(x)$ .

Let  $L$  be the linearized operator  $\mathcal{L}'(S(x); \mathbf{k}_c)$  of (3.1) with respect to  $S(x)$ .

2) The spectral set of  $L$  consists of two sets  $\sigma_1 = \{0\}$  and  $\sigma_2 \subset \{\lambda \in \mathbf{C}; \operatorname{Re}(\lambda) < -\gamma\}$  for a positive constant  $\gamma$ .

**Remark 3.1.** 0 is necessarily a spectrum of  $L$  because (3.1) has a translation invariance and  $LS_x = 0$  holds.

Let  $Q$  and  $R$  be projections corresponding to the spectral sets  $\sigma_1$  and  $\sigma_2$ , respectively. That is,  $Q := \frac{1}{2\pi i} \int_{\Gamma} (\lambda - L)^{-1} d\lambda$  and  $R := Id - Q$ , where  $\Gamma$  is a circle around 0 inside  $\{\lambda \in \mathbf{C}; \operatorname{Re}(\lambda) > -\gamma\}$  and  $Id$  denotes the identity. Define  $E := QX$ ,  $E^\perp := RX$ . Assume

3)  $E = \operatorname{span}\{S_x, \phi_1, \dots, \phi_m\}$  for  $\phi_j \in X$ .

**Remark 3.2.**  $\phi_j \in E$  are the generalized eigenfunctions for 0 eigenvalue. If  $E = \operatorname{span}\{S_x\}$ , 0 is called simple, and if all  $\phi_j$  are eigenfunctions for 0 eigenvalue, it is called semi-simple.

Let  $\mathcal{M} := \{S(x - p); p \in \mathbf{R}^1\}$ . Then we have

**Proposition 3.1.** If  $\mathbf{u}$  is close to  $\mathcal{M}$ , there exist unique  $p \in \mathbf{R}^1$ ,  $\mathbf{r} = (r_1, \dots, r_m) \in \mathbf{R}^m$  and  $\mathbf{w} \in E^\perp$  such that

$$\mathbf{u} = \tau(p)\{S + \langle \mathbf{r}, \phi \rangle + \mathbf{w}\},$$

where  $\tau$  is the translation operator with  $\tau(p)\mathbf{u} := \mathbf{u}(x - p)$  and  $\langle \mathbf{r}, \phi \rangle := \sum_{j=1}^m r_j \phi_j(x)$  with  $\phi = (\phi_1, \dots, \phi_m)$ .

Using the transformation in the neighborhood of  $\mathcal{M}$ , we can rewrite the equation (3.1) of  $\mathbf{u} \in X$  by the equation of  $(p, \mathbf{r}, \mathbf{w}) \in \mathbf{R}^1 \times \mathbf{R}^m \times E^\perp$ .

Let  $\mathbf{k} = \mathbf{k}_c + \boldsymbol{\eta}$ , where  $\boldsymbol{\eta} = (\eta_1, \eta_2)$ . Then the equation of  $(p, \mathbf{r}, \mathbf{w})$  becomes that of the form of

$$(3.2) \quad \begin{cases} \dot{p} &= H_1(\mathbf{r}, \mathbf{w}; \boldsymbol{\eta}), \\ \dot{\mathbf{r}} &= H_2(\mathbf{r}, \mathbf{w}; \boldsymbol{\eta}), \\ \mathbf{w}_t &= L\mathbf{w} + H_3(\mathbf{r}, \mathbf{w}; \boldsymbol{\eta}), \end{cases}$$

where  $\dot{\cdot} = \frac{d}{dt}$  and  $H_j(\mathbf{r}, \mathbf{w}; \boldsymbol{\eta})$  are some functions. We specially note that all  $H_j(\mathbf{r}, \mathbf{w}; \boldsymbol{\eta})$  in (3.2) do not include  $p$  variable. Hence we may only consider the equation of  $(\mathbf{r}, \mathbf{w})$

$$(3.3) \quad \begin{cases} \dot{\mathbf{r}} &= H_2(\mathbf{r}, \mathbf{w}; \boldsymbol{\eta}), \\ \mathbf{w}_t &= L\mathbf{w} + H_3(\mathbf{r}, \mathbf{w}; \boldsymbol{\eta}). \end{cases}$$

Let  $X^\omega$  be the fractional power space imbedded into  $C^1(\mathbf{R}^1)$ .

**Theorem 3.1.** ([5]) There are positive constants  $\bar{\eta}$  and  $\bar{r}$  such that for any  $\boldsymbol{\eta}$  and  $\mathbf{r}$  with  $|\boldsymbol{\eta}| < \bar{\eta}$  and  $|\mathbf{r}| < \bar{r}$  there exists a function  $\sigma = \sigma(\mathbf{r}; \boldsymbol{\eta}) \in E^\perp$  with  $\|\sigma(\mathbf{r}; \boldsymbol{\eta})\|_\omega \leq C(|\mathbf{r}|^2 + |\boldsymbol{\eta}|)$  such that the set  $\mathcal{M}_1(\boldsymbol{\eta}) := \{(\mathbf{r}, \sigma(\mathbf{r}; \boldsymbol{\eta})) \in \mathbf{R}^m \times E^\perp; |\mathbf{r}| < \bar{r}\}$  is locally positively invariant and exponentially attractive with respect to the dynamics of (3.3).

If we define the set  $\mathcal{M}(\boldsymbol{\eta}) := \{\tau(p)\{S + \langle \mathbf{r}, \boldsymbol{\phi} \rangle + \sigma(\mathbf{r}; \boldsymbol{\eta})\}; p \in \mathbf{R}^1, |\mathbf{r}| < \bar{r}\}$ , Theorem 3.1 means  $\mathcal{M}(\boldsymbol{\eta})$  is an exponentially attractive positively invariant set for the equation (3.1), which is locally in  $\mathbf{r}$  but globally defined in the space variable  $p$ .

In the next section, we apply the results to the dynamics of pulses in the Gray-Scott model.

#### 4. DYNAMICS OF PULSES IN THE CASE OF MULTIPLE DEGENERACY

As in mentioned in Section 2, the saddle-node type bifurcation causes the splitting behavior and the Jordan block type singularity does the bifurcation of traveling pulses.

In this section, to see the splitting dynamics of traveling pulses, we assume above two types of bifurcation occur at the same time. That is, we assume:

4) For the equation (3.1), there is  $\mathbf{k} = \mathbf{k}_c$  such that at  $\mathbf{k} = \mathbf{k}_c$  there exist eigenfunctions  $\xi(x)$  and  $\psi(x)$  such that  $E = \text{span}\{S_x, \xi, \psi\}$  and  $L\xi = 0$ ,  $L\psi = -S_x$  are satisfied, and  $\xi$  is even while  $\psi$  is odd.

**Remark 4.1.** The existence of an eigenfunction  $\xi$  causes the saddle-node type bifurcation ([13], [4]) while  $\psi$  does the bifurcation of traveling pulses with pitchfork type ([3]).

**Remark 4.2.** The assumption 4) is numerically checked for the Gray-Scott model (2.1). In fact, the parameter values at which the assumption 4) holds is found in the parameter space  $(A, k)$  as in Fig4.

Figure 4: The parameter space  $(A, k)$  for the equation (2.1).  $k_S$ ,  $k_T$  and  $k_j$  are stated in Section 2.

Let  $L^*$  be the adjoint operator of  $L$ . Then similar properties to  $L$  hold for  $L^*$ . That is, there exist  $\phi^*(x)$ ,  $\xi^*(x)$

and  $\psi^*(x)$  such that  $L^*\phi^* = L^*\xi^* = 0$  and  $L^*\psi^* = -\phi^*$ .  $\phi^*$  and  $\psi^*$  are odd and  $\xi^*$  is even.

**Remark 4.3.** By the normalization of

$$\langle \psi, S_x \rangle_{L^2} = \langle \psi, \psi^* \rangle_{L^2} = 0, \quad \langle \xi, \xi^* \rangle_{L^2} = \langle S_x, \psi^* \rangle_{L^2} = 1$$

all functions are uniquely determined (e.g. [3]). We note that

$$\langle S_x, \xi^* \rangle_{L^2} = \langle \xi, \phi^* \rangle_{L^2} = \langle S_x, \phi^* \rangle_{L^2} = 0, \quad \langle \psi, \phi^* \rangle_{L^2} = 1$$

hold automatically.

We apply Theorem 3.1. Let  $\mathbf{k} = \mathbf{k}_c + \boldsymbol{\eta}$ , where  $\boldsymbol{\eta} = (\eta_1, \eta_2)$  and let  $\mathbf{r} = (q, r) \in \mathbf{R}^2$ ,  $\boldsymbol{\phi} = (\xi, \psi)$ . Then by investigating the flow on the set  $\mathcal{M}(\boldsymbol{\eta})$ , we have

**Theorem 4.1.** ([5]) Under the assumptions 1), 2), 4), there are positive constants  $\bar{q}$ ,  $\bar{r}$  and  $\bar{\eta}$  such that the solution  $\mathbf{u} = \mathbf{u}(t, x)$  of (3.1) is represented by

$$(4.1) \quad \mathbf{u}(t, x) = S(x-p) + q\psi(x-p) + r\xi(x-p) + O(|q|^2 + |r|^2 + |\boldsymbol{\eta}|)$$

and  $(p, q, r)$  satisfy

$$(4.2) \quad \begin{cases} \dot{p} &= q + O(|q|^2 + |r|^2 + |\boldsymbol{\eta}|), \\ \dot{q} &= -\{N_1 q^2 - N_2 r + n_1\}q + O(|q|^4 + |r|^{\frac{8}{3}} + |\boldsymbol{\eta}|^2), \\ \dot{r} &= M_1 r^2 - M_2 q^2 - n_2 + O(|q|^3 + |r|^3 + |\boldsymbol{\eta}|^{\frac{3}{2}}) \end{cases}$$

uniformly for  $p \in \mathbf{R}^1$ ,  $|q| < \bar{q}$  and  $|r| < \bar{r}$ ,  $|\boldsymbol{\eta}| < \bar{\eta}$ , where  $N_j$ ,  $M_j$  and  $a_j$ ,  $b_j$  are constants and  $n_1 := a_1 \eta_1 + a_2 \eta_2$ ,  $n_2 := b_1 \eta_1 + b_2 \eta_2$ .

**Remark 4.4.** All constants in (4.2) are determined in explicit ways but we do not give them in this paper while they will be given in detail in the forthcoming paper [5].

**Remark 4.5.** Constants  $M_j$  and  $N_j$  are all positive in the Gray-Scott model (2.1) and  $M_1 < 1$ , which is numerically confirmed under the appropriate coefficients.

From the above remark, we assume:

5) Constants  $M_j$  and  $N_j$  are all positive and  $M_1 < 1$  in (4.2).

Let us consider the dynamics of solutions of the leading terms of (4.2):

$$(4.3) \quad \begin{cases} \dot{p} &= q, \\ \dot{q} &= -\{N_1 q^2 - N_2 r + (a_1 \eta_1 + a_2 \eta_2)\}q, \\ \dot{r} &= M_1 r^2 - M_2 q^2 - (b_1 \eta_1 + b_2 \eta_2). \end{cases}$$

We can investigate all possible bifurcation diagrams from (4.3), but in this paper we only consider the case  $a_1 > 0 > a_2$ ,  $b_1 > 0 > b_2$ . In this case, two lines  $l_1 := \{(\eta_1, \eta_2); a_1 \eta_1 + a_2 \eta_2 = 0\}$  and  $l_2 := \{(\eta_1, \eta_2); b_1 \eta_1 + b_2 \eta_2 = 0\}$  intersect as in Fig5 in the parameter space  $(\eta_1, \eta_2)$ . Specially, when we change the parameter along the arrow  $\mathbf{l}$  in Fig5, the bifurcation diagram on the equilibria of (4.3) becomes as Fig6. In Fig6, branches with  $\pm P_0 = (0, \pm r)$  denote equilibria with  $q = 0$  and a positive and negative  $r$  component respectively. The branches with  $\pm P_f = \pm(q_f, r)$  and

Figure 5: Two lines  $l_1$  and  $l_2$  in the parameter space  $(\eta_1, \eta_2)$ .

Figure 6: The bifurcation diagram on the equilibria of (4.3) when the parameter moves along the arrow  $l$  in Fig5.

Figure 7: The bifurcation diagram on the equilibria of (4.3) near the point  $B_1$  by numerics with parameters  $N_1 = 0.8$ ,  $N_2 = 1.0$ ,  $M_1 = 0.1$ ,  $M_2 = 0.1$ ,  $a_1 = 1.0$ ,  $a_2 = -0.5$ ,  $b_1 = 0.1$ ,  $b_2 = -0.1$  and  $\eta_2 = -0.3$ .

$\pm P_s = \pm(q_s, r)$  denote equilibria with  $0 < q_s < q_f$ . Stabilities of equilibria are also calculated easily. Specially the stability along the branch  $+P_s$  change from stable focuses to unstable focuses at a point, say  $B_1$ . In the parameter region of unstable focuses, amplitudes of almost all solutions become large, which means the beginning of split. In fact, as discussed in Section 8.5 of [9], when  $M_j$  and  $N_j$  are positive and  $M_1 < 1$ , the stable traveling pulses  $P_f$  lose the stability by subcritical Hopf bifurcation. It is the case of this paper by the assumption 5).

Fig7 is a typical example of the bifurcation diagram in the neighborhood of  $B_1$  by numerics. In the figure, solid lines denote stable equilibria, broken lines do unstable ones, white circles correspond to periodic solutions, white boxes do pitchfork bifurcation points, black boxes do Hopf bifurcation points.

Let us come back to the Gray-Scott model. In the Gray-Scott model, the spatial profiles of eigenfunctions  $\xi(x)$  and  $\psi(x)$  are as in Fig8 (c.f. [13], [4], [3]).

Figure 8: Spatial profiles of eigenfunctions  $\xi(x)$  and  $\psi(x)$ .

Since  $\xi(x)$  has a negative dent in the middle, it will accelerate the splitting of solutions  $u$  if  $r$  increases in the representation (4.1). On the other hand,  $q$  denotes the velocity of pulses because  $\dot{p} = q$  in (4.3). Therefore, the branch  $+P_0$  corresponds to stationary solutions with dimple and  $-P_0$  does non-dimply solutions.  $P_f$  corresponds to faster traveling pulses and  $P_s$  does slower ones. Specially, equilibria  $+P_s$  change the stability from stable focuses to unstable ones at  $B_1$ . Unstable focuses appearing in the neighborhood of  $B_1$  cause the splitting of traveling pulses. In fact, we can numerically observe in Fig9 that solutions asymptotically converge stable traveling pulses with oscillation under parameters corresponding to stable focuses ( (B) in Fig6) and that solutions split with oscillation under parameters of unstable focuses ( (A) in Fig6). Thus, we can analyze the dynamics of moving pulses by constructing invariant manifolds globally in spacial variables.
