Potentially generic polynomial

Toru KOMATSU

§ 1. Introduction

Recently many mathematicians constructed generic polynomials (Hashimoto-Miyake [4], Hoshi [6], Ledet [13], Nakano [15], Rikuna [17], Smith [22],...). In some cases the genericities of the polynomials are guaranteed by some useful sufficient conditions (e.g., Kemper [8], Kemper-Mattig [9] and see also Jensen-Ledet-Yui [7]). In this paper we obtain a necessary condition so that a regular polynomial is generic. A regular polynomial f is potentially generic over a field k if f is generic over a finite extension of k. We present a criterion whether a regular cyclic polynomial is potentially generic or not. This shows that some numerical regular polynomials are not generic. We also study the arithmetic of some numerical regular polynomials due to certain invariants d(t), $\lambda(t)$ and $\mu(t)$.

We first recall some notions on the generic polynomial (cf. Jensen-Ledet-Yui [7]) and introduce a new concept a potentially generic polynomial. Let k be a field and G a finite group. The rational function field $k(t_1, t_2, \ldots, t_m)$ over k with mvariables t_1, t_2, \ldots, t_m is denoted by $k(\mathfrak{t})$ where $\mathfrak{t} = (t_1, t_2, \ldots, t_m)$. For a polynomial $F(X) \in K[X]$ over a field K let us denote by $\operatorname{Spl}_K F(X)$ the minimal splitting field of F(X) over K. We say a polynomial $F(\mathfrak{t}, X) \in k(\mathfrak{t})[X]$ is a k-regular Gpolynomial or a regular polynomial for G over k if $L = \operatorname{Spl}_{k(\mathfrak{t})}F(\mathfrak{t}, X)$ is a Galois extension with $\operatorname{Gal}(L/k(\mathfrak{t})) \simeq G$ and $L \cap \overline{k} = k$ where \overline{k} is an algebraic closure of k. For example, if n is a positive integer greater than 2, then the Kummer polynomial $X^n - t \in \mathbb{Q}(t)[X]$ is a regular polynomial for the cyclic group \mathcal{C}_n of order n not over \mathbb{Q} but over $\mathbb{Q}(\zeta_n)$ where ζ_n is a primitive n-th root of unity in $\overline{\mathbb{Q}}$. A k-regular G-polynomial $F(\mathfrak{t}, X) \in k(\mathfrak{t})[X]$ is called to be generic over k if $F(\mathfrak{t}, X)$ yields all the Galois *G*-extensions containing *k*, that is, for every Galois extension L/K with $\operatorname{Gal}(L/K) \simeq G$ and $K \supseteq k$ there exists a *K*-specialization $\mathfrak{a} = (a_1, a_2, \ldots, a_m), a_i \in K$ so that $L = \operatorname{Spl}_K F(\mathfrak{a}, X)$. We say that a *k*-regular *G*polynomial $F(\mathfrak{t}, X) \in k(\mathfrak{t})[X]$ is potentially generic over *k* when $F(\mathfrak{t}, X)$ is generic over a finite extension of *k*. In this paper we show a necessary condition to hold that a *k*-regular \mathcal{C}_n -polynomial is potentially generic.

Let *n* be a positive integer with $\operatorname{char}(k) \nmid n$. Let $F(\mathfrak{t}, X)$ be an irreducible, monic and *k*-regular \mathcal{C}_n -polynomial and put $L = \operatorname{Spl}_{k(\mathfrak{t})} F(\mathfrak{t}, X)$. We fix a generator σ of $\operatorname{Gal}(L/k(\mathfrak{t})) \simeq \mathcal{C}_n$ and a solution $x \in L$ of the equation $F(\mathfrak{t}, X) = 0$. Then it satisfies that $F(\mathfrak{t}, X) = \prod_{i=0}^{n-1} (X - \sigma^i(x))$ and $L = k(\mathfrak{t}, x)$. Let ζ be a primitive *n*-th root of unity in k^{sep} . For a rational integer $j \in \mathbb{Z}$ we define an element $y_j \in L(\zeta)$ by

$$y_j = \frac{1}{n} \sum_{i=0}^{n-1} \zeta^{-ij} \sigma^i(x),$$

which is called the *j*-th Lagrange resolvent of x for $L/k(\mathfrak{t})$ (cf. [2] § 5.3). Here the element y_j depends on the choice of the elements σ and x. Let $Y_j(\mathfrak{t}, X)$ be a polynomial over $k(\mathfrak{t}, \zeta)$ such that $Y_j(\mathfrak{t}, x) = y_j$. We denote by $g_j(\mathfrak{t}) \in k(\mathfrak{t}, \zeta)$ the product of $(-1)^{j(n-1)}$ and the resultant of the two polynomials $F(\mathfrak{t}, X)$ and $Y_j(\mathfrak{t}, X)$ on the indeterminate X, that is,

$$g_j(\mathfrak{t}) = (-1)^{j(n-1)} \operatorname{Res}_X(F(\mathfrak{t}, X), Y_j(\mathfrak{t}, X)).$$

Proposition 1.1 (Corollary 2.2). We have $L(\zeta) = \text{Spl}_{k(\mathfrak{t},\zeta)}(Y^n - g_j(\mathfrak{t}))$ provided gcd(j,n) = 1 and $y_j \neq 0$.

Note that $F(\mathfrak{t}, X)$ is potentially generic over k if and only if so is $Y^n - g_j(\mathfrak{t})$ over $k(\zeta)$ when gcd(j, n) = 1 and $y_j \neq 0$. By using the $g_j(\mathfrak{t})$ we also study the arithmetic of the field which is obtained as a specialization of $F(\mathfrak{t}, X)$ (see the sections 3 to 5 below). We next consider a condition so that a polynomial $Y^n - g(t)$ is generic over $k(\zeta)$ where $g(t) \in k(t, \zeta)$ is a non-constant rational function over $k(\zeta)$ with one variable t. For an element $\alpha \in \overline{k}$ we denote by $\operatorname{ram}_n(\alpha, g(t))$ the ramification index of the prime divisor $(t - \alpha)$ in the extension $\operatorname{Spl}_{\overline{k}(t,\zeta)}(Y^n - g(t))$ over $\overline{k}(t, \zeta)$.

Theorem 1.2 (Proposition 2.6). If $Y^n - g(t)$ is potentially generic for C_n over $k(\zeta)$, then there exist at most two elements $\alpha \in \overline{k}$ satisfying $\operatorname{ram}_n(\alpha, g(t)) \geq 3$.

In § 2 we study a necessary condition for the genericity of a regular polynomial and prove Proposition 1.1 and Theorem 1.2. In § 3 we calculate the generators of Kummer extensions for some numerical polynomials. In § 4 and § 5 we show that several regular polynomials are not generic by using Proposition 1.1 and Theorem 1.2. We also study the arithmetic of the extensions obtained as the specializations of the polynomials.

Acknowledgement. The author is grateful to Professor Masanari Kida for the information on the results of Spearman-Williams [23] and [24]. He is supported by the 21st Century COE Program "Development of Dynamic Mathematics with High Functionality".

§ 2. Necessary condition for the genericity

Let k be a field and n a positive integer with $\operatorname{char}(k) \nmid n$. For an irreducible, monic and k-regular \mathcal{C}_n -polynomial $F(\mathfrak{t}, X) \in k(\mathfrak{t})[X]$ let L be the extension field $\operatorname{Spl}_{k(\mathfrak{t})}F(\mathfrak{t}, X)$ and σ a generator of $\operatorname{Gal}(L/k(\mathfrak{t})) \simeq \mathcal{C}_n$. We fix a solution $x \in L$ of $F(\mathfrak{t}, X) = 0$. Then it holds that $L = k(\mathfrak{t}, x)$ and $F(\mathfrak{t}, X) = \prod_{i=0}^{n-1} (X - \sigma^i(x))$. Note that $F(\mathfrak{t}, X)$ is potentially generic over k if and only if so is over $k(\zeta)$ where ζ is a primitive n-th root of unity in k^{sep} . Since $L/k(\mathfrak{t})$ is k-regular, $L(\zeta)/k(\mathfrak{t}, \zeta)$ is a $k(\zeta)$ -regular \mathcal{C}_n -extension. Kummer theory implies that there exists an element $y \in L(\zeta)$ so that $L(\zeta) = k(\mathfrak{t}, \zeta, y)$ and $y^n \in k(\mathfrak{t}, \zeta)$. One can make such a $y \in L(\zeta)$ by using the elements $x \in L$ and $\sigma \in \operatorname{Gal}(L/k(\mathfrak{t}))$ as follows (cf. [2] § 5.3). For a rational integer $j \in \mathbb{Z}$ we define

$$y_j = \frac{1}{n} \sum_{i=0}^{n-1} \zeta^{-ij} \sigma^i(x),$$

which is called the *j*-th Lagrange resolvent of x for $L/k(\mathfrak{t})$. Here the element y_j depends on the choice of the elements σ and x. Note that $L \cap k(\mathfrak{t}, \zeta) = k(\mathfrak{t})$ since L is k-regular. There exists an extension $\tilde{\sigma} \in \text{Gal}(L(\zeta)/k(\mathfrak{t}))$ of the action $\sigma \in \text{Gal}(L/k(\mathfrak{t}))$ such that $\tilde{\sigma}(\zeta) = \zeta$ and $\tilde{\sigma}(x) = \sigma(x)$.

Lemma 2.1. We have $\widetilde{\sigma}(y_j) = \zeta^j y_j$ and $y_j^n \in k(\mathfrak{t}, \zeta)$.

Proof. It follows from the definition that

$$\widetilde{\sigma}(y_j) = \frac{1}{n} \sum_{i=0}^{n-1} \zeta^{-ij} \sigma^{i+1}(x) = \frac{1}{n} \sum_{i=0}^{n-1} \zeta^{-(i-1)j} \sigma^i(x) = \zeta^j y_j.$$

ve $y_i^n \in L(\zeta)^{\langle \widetilde{\sigma} \rangle} = k(\mathfrak{t}, \zeta).$

Thus we have $y_j^n \in L(\zeta)^{\langle \tilde{\sigma} \rangle} = k(\mathfrak{t}, \zeta)$.

Let us denote the rational function $y_j^n \in k(\mathfrak{t}, \zeta)$ by $g_j(\mathfrak{t})$. The definition of $g_j(\mathfrak{t})$ is different from that in the Introduction. Lemma 2.4 below will make sure that the two definitions are equivalent to each other.

Corollary 2.2. If
$$gcd(j,n) = 1$$
 and $y_j \neq 0$, then $L(\zeta) = Spl_{k(\mathfrak{t},\zeta)}(Y^n - g_j(\mathfrak{t}))$.

Proof. It follows from gcd(j, n) = 1 and $y_j \neq 0$ that $[k(\mathfrak{t}, \zeta, y_j) : k(\mathfrak{t}, \zeta)] = n$. Since $y_j \in L(\zeta)$ and $[L(\zeta) : k(\mathfrak{t}, \zeta)] = n$, we have $L(\zeta) = k(\mathfrak{t}, \zeta, y_j) = \operatorname{Spl}_{k(\mathfrak{t}, \zeta)}(Y^n - g_j(\mathfrak{t}))$.

REMARK 2.3. When $\zeta \notin k$ and n is a prime number, one has that $y_1 = n^{-1} \sum_{i=1}^{n-1} \zeta^{-i} (\sigma^i(x) - x) \neq 0.$

The following lemma is useful to calculate the element $g_j(\mathfrak{t}) \in k(\mathfrak{t}, \zeta)$. Let $Y_j(\mathfrak{t}, X)$ be a polynomial in $k(\mathfrak{t}, \zeta)[X]$ such that $Y_j(\mathfrak{t}, x) = y_j$. We define the resultant $\operatorname{Res}_X(p_1(X), p_2(X))$ of two polynomials $p_1(X) = a \prod_{i=1}^l (X - \alpha_i)$ and $p_2(X) = b \prod_{j=1}^m (X - \beta_j)$ by

$$\operatorname{Res}_X(p_1(X), p_2(X)) = a^m \prod_{i=1}^l p_2(\alpha_i) = (-1)^{lm} b^l \prod_{j=1}^m p_1(\beta_j).$$

Lemma 2.4. We have

$$g_j(\mathfrak{t}) = (-1)^{j(n-1)} \operatorname{Res}_X(F(\mathfrak{t}, X), Y_j(\mathfrak{t}, X)).$$

Proof. It follows from the definition that

$$N_{L(\zeta)/k(\mathfrak{t},\zeta)}(y_j) = \prod_{i=0}^{n-1} Y_j(\mathfrak{t}, \widetilde{\sigma}^i(x)) = \operatorname{Res}_X(F(\mathfrak{t}, X), Y_j(\mathfrak{t}, X)).$$

On the other hand, Lemma 2.1 implies that

$$N_{L(\zeta)/k(\mathfrak{t},\zeta)}(y_j) = \prod_{i=0}^{n-1} \widetilde{\sigma}^i(y_j) = \prod_{i=0}^{n-1} \zeta^{ji} y_j = (-1)^{j(n-1)} y_j^n = (-1)^{j(n-1)} g_j(\mathfrak{t}).$$

Thus the equation of the assertion holds.

Corollary 2.2 and Lemma 2.4 verify Proposition 1.1.

REMARK 2.5. There are several formulas for the resultant, e.g., the determinant of Sylvester's matrix (cf. [1] § 3.3).

Let $g(t) \in k(t, \zeta)$ be a non-constant rational function over $k(\zeta)$ with one variable t. We give a necessary condition so that $Y^n - g(t)$ is generic over $k(\zeta)$. As defined in the Introduction we denote by $\operatorname{ram}_n(\alpha, g(t))$ the ramification index of the prime divisor $(t - \alpha)$ in the extension $\operatorname{Spl}_{\overline{k}(t,\zeta)}(Y^n - g(t))/\overline{k}(t,\zeta)$ for an element $\alpha \in \overline{k}$.

Proposition 2.6 (Theorem 1.2). If the set $\{\alpha \in \overline{k} | \operatorname{ram}_n(\alpha, g(t)) \geq 3\}$ has at least three elements, then the polynomial $Y^n - g(t) \in k(t, \zeta)[Y]$ is not potentially generic for \mathcal{C}_n over $k(\zeta)$.

For the proof of Proposition 2.6 we use the abc theorem for the function field, which is a corollary of Riemann-Hurwitz formula. For a non-constant rational function $u = u(t) \in \overline{k}(t)$ let us consider a map $u : \mathbb{P}^1(\overline{k}) \to \mathbb{P}^1(\overline{k}), a \mapsto u(a)$. For an element $b \in \mathbb{P}^1(\overline{k}) - \{0, \infty\}$ we denote by Z(b, u) the union set $u^{-1}(\{0, b, \infty\})$ of the inverse images of three points 0, b and ∞ by the map u.

Lemma 2.7. If the extension $\overline{k}(t)/\overline{k}(u)$ is separable, then $[\overline{k}(t) : \overline{k}(u)] \leq$ $\sharp Z(b, u) - 2.$

Proof. Riemann-Hurwitz formula implies that

$$-2 \ge -2d_u + \sum_{a \in \mathbb{P}^1(\overline{k})} (e_u(a) - 1) \\\ge -2d_u + \sum_{a \in Z(b,u)} (e_u(a) - 1) \\= -2d_u + 3d_u - \sharp Z(b,u) \\= d_u - \sharp Z(b,u)$$

where $d_u = [\overline{k}(t) : \overline{k}(u)]$ and $e_u(a)$ is the ramification index of u at $a \in \mathbb{P}^1(\overline{k})$. Thus we have $d_u \leq \sharp Z(b, u) - 2$.

Proof of Proposition 2.6. Now suppose $Y^n - g(t)$ is potentially generic over $k(\zeta)$, then $Y^n - g(t)$ is generic over \overline{k} . One may assume that g(t) is a monic polynomial over \overline{k} of the form $g(t) = \prod_{i=1}^{l} (t - \alpha_i)^{m_i}$ where $\alpha_i \in \overline{k}$ and $m_i = \operatorname{ord}_{\alpha_i} g(t)$ are positive integers. Let s be an indeterminate and $K = \overline{k}(s)$. Due to the genericity of $Y^n - g(t)$ there exists a rational function $h(s) \in K$ such that $\operatorname{Spl}_K(Z^n - s) =$ $\operatorname{Spl}_{K}(Y^{n} - g(h(s)))$, that is, the Kummer extension $\operatorname{Spl}_{K}(Z^{n} - s)$ should be obtained as a suitable specialization $t = h(s) \in K$. It follows from Kummer theory that $g(h(s))/s^{j} \in K^{n}$ for an integer $j \in \mathbb{Z}$. Let $h_{1}(s)$ and $h_{2}(s)$ be polynomials in $\overline{k}[s]$ with no common zeros such that $h(s) = h_{1}(s)/h_{2}(s)$. Then we have $h_{2}(s)^{-m}s^{-j}\prod_{i=1}^{l}(h_{1}(s) - \alpha_{i}h_{2}(s))^{m_{i}} \in K^{n}$ where m is equal to the degree $\deg_{t}g(t) = \sum_{i=1}^{l} m_{i}$ of the polynomial g(t). Since α_{i} are distinct, the polynomials $h_{1}(s) - \alpha_{i}h_{2}(s)$ and $h_{2}(s)$ are relatively prime to each other. Thus there exist polynomials $p_{i}(s) \in \overline{k}[s]$ and non-negative integers $j_{i} \in \mathbb{Z}$ such that $h_{1}(s) - \alpha_{i}h_{2}(s) = s^{j_{i}}p_{i}(s)^{r_{i}}$ and $p_{i}(0) \neq 0$ where $r_{i} = \operatorname{ram}_{n}(\alpha_{i}, g(t))$. Note that $j_{i} = \operatorname{ord}_{0}(h_{1}(s) - \alpha_{i}h_{2}(s))$. Thus one may assume $j_{2} = j_{3} = 0$. Here it holds that $(\alpha_{2} - \alpha_{3})s^{j_{1}}p_{1}(s)^{r_{1}} + (\alpha_{3} - \alpha_{1})p_{2}(s)^{r_{2}} + (\alpha_{1} - \alpha_{2})p_{3}(s)^{r_{3}} = 0$. Let u_{1} and u_{2} be rational functions in K such that

$$u_1 = \frac{(\alpha_2 - \alpha_3)s^{j_1}p_1(s)^{r_1}}{(\alpha_1 - \alpha_2)p_3(s)^{r_3}}, \quad u_2 = \frac{(\alpha_3 - \alpha_1)p_2(s)^{r_2}}{(\alpha_1 - \alpha_2)p_3(s)^{r_3}}.$$

Then one has $u_1 + u_2 + 1 = 0$, which means that $\overline{k}(u_1) = \overline{k}(u_2)$. Let M be the maximal separable extension of $\overline{k}(u_i)$ contained in K, and q be the degree of the purely inseparable extension K/M. Then there exist rational functions $\widetilde{u}_i(s) \in K$ such that $\widetilde{u}_i(s^q) = u_i(s)$ for i = 1 and 2. Since $p_1(s)$, $p_2(s)$ and $p_3(s)$ are relatively prime to each other, we have $\widetilde{p}_i(s^q) = p_i(s)$ for some polynomials $\widetilde{p}_i(s) \in \overline{k}[s]$, respectively. In fact, r_i are prime to q since r_i are divisors of n. Then $K/\overline{k}(\widetilde{u}_1)$ is a separable extension. Let us denote by d_i the degrees $\deg_s \widetilde{p}_i(s)$ of the polynomials $\widetilde{p}_i(s) \in \overline{k}[s]$, respectively. It follows from $\widetilde{u}_1 + 1 = -\widetilde{u}_2$ that $\sharp Z(-1, \widetilde{u}_1) \leq 1 + \sum_{i=1}^3 d_i$. Here one has that $[K : \overline{k}(\widetilde{u}_i)] = \max\{r_1d_1 + j_1/q, r_2d_2, r_3d_3\} \geq (r_1d_1 + r_2d_2 + r_3d_3)/3$. Lemma 2.7 implies

$$r_1d_1 + r_2d_2 + r_3d_3 \le 3[K:\overline{k}(\widetilde{u}_1)] \le 3(d_1 + d_2 + d_3 - 1).$$

This means that $3 + \sum_{i=1}^{3} (r_i - 3)d_i \leq 0$, which is impossible provided $r_i \geq 3$ for i = 1, 2 and 3. Hence we conclude that the set $\{\alpha \in \overline{k} | \operatorname{ram}_n(\alpha, g(t)) \geq 3\}$ has at most two elements.

The number $\operatorname{ram}_n(\alpha, g(t))$ is equal to the minimal positive integer r such that $\operatorname{rord}_{\alpha}g(t) \in n\mathbb{Z}$ where $\operatorname{ord}_{\alpha}g(t)$ is the order at α of g(t). We define a positive integer

 $\operatorname{ram}_n(\infty, g(t))$ to be the minimal positive divisor r of n satisfying $\operatorname{rord}_{\infty}g(t) \in n\mathbb{Z}$ as for the case $\alpha \in \overline{k}$.

Corollary 2.8. If the set $\{\alpha \in \overline{k} \cup \{\infty\} | \operatorname{ram}_n(\alpha, g(t)) \geq 3\}$ has at least three elements, then the polynomial $Y^n - g(t)$ is not potentially generic for \mathcal{C}_n over $k(\zeta)$.

Proof. Let α_1, α_2 and $\alpha_3 \in \overline{k} \cup \{\infty\}$ be distinct three elements which satisfy ram_n $(\alpha, g(t)) \geq 3$. It follows from Proposition 2.6 that one may assume $\alpha_3 = \infty$. For an element $a \in \overline{k}$ with $a \notin \{\alpha_1, \alpha_2, \alpha_3\}$ we put $g_a(t) = g(1/t + a) \in k(t, \zeta, a)$. Then the set $\{\alpha \in \overline{k} | \operatorname{ram}_n(\alpha, g_a(t)) \geq 3\}$ has distinct three elements $1/(\alpha_i - a) \in \overline{k}$ for i = 1, 2 and 3. Proposition 2.6 implies that $Y^n - g_a(t)$ is not potentially generic over $k(\zeta, a)$. Here the potential genericity of $Y^n - g(t)$ over $k(\zeta)$ is equivalent to that of $Y^n - g_a(t)$ over $k(\zeta, a)$. Thus $Y^n - g(t)$ is not potentially generic over $k(\zeta)$.

For an irreducible, monic and k-regular C_n -polynomial $F(t, X) \in k(t)[X]$ we denote by $e_3(F)$ the sum of the degrees of the prime divisors of k(t) whose ramification indices in the extension $\operatorname{Spl}_{k(t)}F(t,X)/k(t)$ are greater than 2.

Corollary 2.9. If $e_3(F) \ge 3$, then F(t, X) is not potentially generic for C_n over k.

Proof. Since F(t, X) is regular over k, one sees that the number $e_3(F)$ is equal to $\sharp\{\alpha \in \overline{k} \cup \{\infty\} | \operatorname{ram}_n(\alpha, g_F(t)) \geq 3\}$ where $g_F(t)$ is the rational function described in this section so that $\operatorname{Spl}_{k(t,\zeta)} F(t, X) = \operatorname{Spl}_{k(t,\zeta)} (Y^n - g_F(t))$.

§ 3. Some numerical examples of general degree cases

Let $n \in \mathbb{Z}$ be a rational integer greater than 2 and ζ a primitive *n*-th root of unity in $\overline{\mathbb{Q}}$ and $\omega = \zeta + \zeta^{-1}$. Rikuna [16] defined a polynomial

$$R_n(t,X) = \frac{\zeta^{-1}(X-\zeta)^n - \zeta(X-\zeta^{-1})^n}{\zeta^{-1}-\zeta} - t\frac{(X-\zeta)^n - (X-\zeta^{-1})^n}{\zeta^{-1}-\zeta},$$

which is a regular C_n -polynomial over $k = \mathbb{Q}(\omega)$. It is already shown that $R_n(t, X)$ is generic over k if n is odd (Rikuna [16]) and that $R_n(t, X)$ is generic not over kbut over $k(\zeta)$ when n is even (Komatsu [11]). Thus the polynomials $R_n(t, X)$ with even n are examples of the non-generic but potentially generic polynomials. Let L be the field $\operatorname{Spl}_{k(t)}R_n(t,X)$ and x a solution in L of $R_n(t,X) = 0$. Then one sees that L = k(t,x) and $\operatorname{Gal}(L/k(t)) = \langle \sigma \rangle \simeq C_n$ where

$$\sigma^{i}(x) = \frac{(\zeta^{i-1} - \zeta)x - (\zeta^{i} - 1)}{(\zeta^{i} - 1)x - (\zeta^{i+1} - \zeta^{-1})}$$

(cf. Rikuna [16], Komatsu [11]). Let y_j be the *j*-th Lagrange resolvent of x for L/k(t), that is, $y_j = n^{-1} \sum_{i=0}^{n-1} \zeta^{-ij} \sigma^i(x)$.

Proposition 3.1. For a rational integer $j \in \mathbb{Z}$ with $1 \leq j \leq n-1$ we have $y_j^n = (t-\zeta)^j (t-\zeta^{-1})^{n-j}$ and $y_0 = t$.

We use the following lemma.

Lemma 3.2. For a rational integer $j \in \mathbb{Z}$ with $0 \leq j \leq n-1$ we have

$$\frac{1}{n}\sum_{i=0}^{n-1}\zeta^{-ij}\frac{\zeta^{i-1}Z-\zeta}{\zeta^{i}Z-1} = \begin{cases} \frac{\zeta^{-1}Z^n-\zeta}{Z^n-1} & \text{if } j=0, \\ \frac{(\zeta^{-1}-\zeta)Z^j}{Z^n-1} & \text{otherwise.} \end{cases}$$

Proof. It follows from the definition that

$$\frac{\frac{1}{n}\sum_{i=0}^{n-1}\zeta^{-ij}\frac{\zeta^{i-1}Z-\zeta}{\zeta^{i}Z-1}}{=\frac{1}{n}\sum_{i=0}^{n-1}\zeta^{-ij}\frac{\zeta^{i-1}Z-\zeta}{Z^n-1}\sum_{m=0}^{n-1}(\zeta^{i}Z)^m \\
=\frac{1}{n(Z^n-1)}\left(\zeta^{-1}\sum_{m=0}^{n-1}\sum_{i=0}^{n-1}\zeta^{i(m+1-j)}Z^{m+1}-\zeta\sum_{m=0}^{n-1}\sum_{i=0}^{n-1}\zeta^{i(m-j)}Z^m\right).$$

Note that $\sum_{i=0}^{n-1} \zeta^{im}$ is equal to n if $m \equiv 0 \pmod{n}$ and 0 otherwise. Thus we have the equation of the assertion.

Proof of Proposition 3.1. By substituting $Z = (x - \zeta)/(x - \zeta^{-1})$ in the equation of Lemma 3.2 we have $y_0 = (\zeta^{-1}(x - \zeta)^n - \zeta(x - \zeta^{-1})^n)/((x - \zeta)^n - (x - \zeta^{-1})^n) = t$. Here one has

$$t - \zeta^{\pm 1} = \frac{(\zeta^{-1} - \zeta)(x - \zeta^{\pm 1})^n}{(x - \zeta)^n - (x - \zeta^{-1})^n},$$

respectively. When $1 \le j \le n-1$, Lemma 3.2 with $Z = (x - \zeta)/(x - \zeta^{-1})$ implies that

$$y_j^n = \frac{(\zeta^{-1} - \zeta)^n (x - \zeta)^{jn} (x - \zeta^{-1})^{(n-j)n}}{((x - \zeta)^n - (x - \zeta^{-1})^n)^n} = (t - \zeta)^j (t - \zeta^{-1})^{n-j}.$$

Corollary 3.3. We have $L(\zeta) = \operatorname{Spl}_{k(t,\zeta)}(Y^n - (t-\zeta)/(t-\zeta^{-1}))$. In particular, $R_n(t,X)$ is generic over $k(\zeta)$ and potentially generic over k.

Proof. Corollary 2.2 and Proposition 3.1 imply that

$$L(\zeta) = \operatorname{Spl}_{k(t,\zeta)}(Y^n - (t - \zeta)(t - \zeta^{-1})^{n-1}) = \operatorname{Spl}_{k(t,\zeta)}(Y^n - (t - \zeta)/(t - \zeta^{-1})).$$

Since $(t - \zeta)/(t - \zeta^{-1})$ is linear fractional, it follows from Kummer theory that $Y^n - (t - \zeta)/(t - \zeta^{-1})$ is generic over $k(\zeta)$ and so is $R_n(t, X)$.

Let $k = \mathbb{Q}(\omega)$ be as in the case of $R_n(t, X)$. For an even integer n greater than 2, Hashimoto and Rikuna [5] defined a polynomial $HR_n(\mathfrak{t}, X) \in k(\mathfrak{t})[X]$ with two parameters $\mathfrak{t} = (t_1, t_2)$ such that

$$HR_{n}(\mathfrak{t}, X) = X^{n} + \sum_{i=1}^{(n-2)/2} B(n, i) (T_{1}t_{2})^{i} X^{n-2i} - (\omega^{2} - 4) T_{1}^{(n-2)/2} t_{2}^{n/2} \in k(t_{1}, t_{2})[X]$$

where $T_1 = t_1^2 - \omega t_1 + 1$ and $B(n,i) = \binom{n-i-1}{i-1} + \binom{n-i}{i}$. Here $\binom{m_1}{m_2}$ denotes the binomial coefficient $m_1!/(m_2!(m_1-m_2)!)$.

Proposition 3.4 (Hashimoto-Rikuna [5]). The polynomial $HR_n(\mathfrak{t}, X)$ is kgeneric for C_n .

We calculate the rational function $g_j(\mathfrak{t})$ for $HR_n(\mathfrak{t}, X)$.

Lemma 3.5. We have

$$\operatorname{Spl}_{k(\mathfrak{t},\zeta)}HR_{n}(\mathfrak{t},X) = \operatorname{Spl}_{k(\mathfrak{t},\zeta)}(Y^{n} - (T_{1}t_{2})^{n/2}\frac{t_{1}-\zeta}{t_{1}-\zeta^{-1}})$$

Proof. Let us denote $\operatorname{Spl}_{k(\mathfrak{t})} HR_n(\mathfrak{t}, X)$ by L. For a solution z_1 of $Z^n - (T_1 t_2)^{n/2} (t_1 - \zeta)/(t_1 - \zeta^{-1}) = 0$ in $\overline{k(\mathfrak{t})}$ we put $z_2 = -T_1 t_2/z_1$. The argument in [5] implies that

$$HR_{n}(\mathfrak{t}, X) = \prod_{i=0}^{n} (X - (\zeta^{i} z_{1} + \zeta^{-i} z_{2})),$$

 $L = k(\mathfrak{t}, z_1 + z_2)$ and that the Galois group $\operatorname{Gal}(L/k(\mathfrak{t}))$ is generated by $\sigma \in \operatorname{Gal}(L/k(\mathfrak{t}))$ such that $\sigma^i(z_1 + z_2) = \zeta^i z_1 + \zeta^{-i} z_2$. Thus the *j*-th Lagrange resolvent y_j is equal to

$$y_j = \begin{cases} z_1 & \text{if } j \equiv 1 \pmod{n}, \\ z_2 & \text{if } j \equiv -1 \pmod{n}, \\ 0 & \text{otherwise.} \end{cases}$$

Hence the element $g_1(\mathfrak{t}) = y_1^n$ is equal to $z_1^n = (T_1 t_2)^{n/2} (t_1 - \zeta) / (t_1 - \zeta^{-1}).$

Corollary 3.6. Let K be a finite number field containing $k = \mathbb{Q}(\omega)$ and \mathfrak{p} a prime ideal of K with $\mathfrak{p} \nmid n$. For an $\mathfrak{a} = (a_1, a_2) \in K^2$ with $(a_1^2 - \omega a_1 + 1)a_2 \neq 0$, the

ramification index of \mathfrak{p} in the extension $\operatorname{Spl}_{K}HR_{n}(\mathfrak{a}, X)/K$ is equal to the order of the rational integer

$$\left(\frac{n}{2}-1\right)\max\left\{\operatorname{ord}_{\mathfrak{p}}(a_{1}^{2}-\omega a_{1}+1),0\right\}+\frac{n}{2}\operatorname{ord}_{\mathfrak{p}}(a_{2})$$

in the additive group $\mathbb{Z}/n\mathbb{Z}$. Here $\operatorname{ord}_{\mathfrak{p}}$ is the \mathfrak{p} -adic additive valuation of K so that $\operatorname{ord}_{\mathfrak{p}}(K^{\times}) = \mathbb{Z}$.

§ 4. Several examples of cubic polynomials

We prepare some lemmas for the calculation of the ramification in the extension over an algebraic number field.

Lemma 4.1 (cf. [3]). Let l be a prime number and \mathfrak{p} a prime ideal of $\mathbb{Q}(\zeta_l)$. Let $c \in \mathbb{Q}(\zeta_l)$ and $z \in \overline{\mathbb{Q}}$ be algebraic numbers such that $z^l = c \neq 0$. (1) When $v_{\mathfrak{p}}(c) \not\equiv 0 \pmod{l}$, the extension $\mathbb{Q}(\zeta_l, z)/\mathbb{Q}(\zeta_l)$ is ramified at \mathfrak{p} . (2) If $v_{\mathfrak{p}}(c) \equiv 0 \pmod{l}$ and $\mathfrak{p} \nmid l$, then $\mathbb{Q}(\zeta_l, z)/\mathbb{Q}(\zeta_l)$ is unramified at \mathfrak{p} . (3) For the case $v_{\mathfrak{p}}(c) = 0$, the prime ideal $\mathfrak{p} = (\zeta_l - 1)$ of $\mathbb{Q}(\zeta_l)$ above l ramifies, remains prime and splits completely in $\mathbb{Q}(\zeta_l, z)/\mathbb{Q}(\zeta_l)$ if and only if the valuation $v_{\mathfrak{p}}(c^{l-1}-1)$ is less than l, equal to l and greater than l, respectively.

Corollary 4.2. Let the notation be as in Lemma 4.1. We assume that there exists an element $\tau \in \text{Gal}(\mathbb{Q}(\zeta_l)/\mathbb{Q})$ of order m such that $N_{\langle \tau \rangle}(c) = \prod_{i=0}^{m-1} \tau^i(c) = 1$. Then the prime ideal $\mathfrak{p} = (\zeta_l - 1)$ of $\mathbb{Q}(\zeta_l)$ above l ramifies, remains prime and splits completely in the extension $\mathbb{Q}(\zeta_l, z)/\mathbb{Q}(\zeta_l)$ if and only if the valuation $v_{\mathfrak{p}}(c^m - 1)$ is less than l, equal to l and greater than l, respectively.

Proof. Since $\mathbf{p} = (\zeta_l - 1)$ is a unique prime ideal of $\mathbb{Q}(\zeta_l)$ above l, we have $\tau(\mathbf{p}) = \mathbf{p}$ and $v_{\mathbf{p}}(c) = v_{\mathbf{p}}(\tau^i(c))$. This implies that $mv_{\mathbf{p}}(c) = v_{\mathbf{p}}(1) = 0$ and $v_{\mathbf{p}}(c) = 0$. Note that $\tau(c) \equiv c \pmod{\mathbf{p}}$ for $\mathcal{O}_{\mathbb{Q}(\zeta_l)}/\mathbf{p} \simeq \mathbb{F}_l$. Thus one has that $c^m \equiv N_{\langle \tau \rangle}(c) \equiv 1$ $(\text{mod } \mathbf{p})$. Since m is a divisor of l-1, we have $c^l - c = c(c^m - 1) \sum_{i=0}^{(l-1)/m-1} c^{mi}$. It holds that $\sum_{i=0}^{(l-1)/m-1} c^{mi} \equiv (l-1)/m \not\equiv 0 \pmod{\mathbf{p}}$. This means that $v_{\mathbf{p}}(c^m - 1) =$ $v_{\mathbf{p}}(c^l - c)$. Hence Lemma 4.1 (3) shows the assertion. \Box

Let us consider a cubic polynomial

$$f_0(t, X) = X^3 - tX^2 - (t+3)X - 1$$

over $\mathbb{Q}(t)$, which is called the simplest cubic polynomial of Shanks type [21]. The discriminant of the polynomial $f_0(t, X)$ is equal to $(t^2 + 3t + 9)^2$. For the relation $f_0(t, X) = R_3(t/3, X)$ one can think that the Rikuna's polynomial $R_n(t, X)$ at the previous section is a generalization of the $f_0(t, X)$. The field $L_0 = \operatorname{Spl}_{\mathbb{Q}(t)} f_0(t, X)$ is a cyclic cubic extension of $\mathbb{Q}(t)$ whose Galois group $\operatorname{Gal}(L_0/\mathbb{Q}(t))$ is generated by an element σ satisfying

$$\sigma(x) = \frac{-x-1}{x} = -x^2 + tx + (t+2), \quad \sigma^2(x) = \frac{-1}{x+1} = x^2 - (t+1)x - 2.$$

The 1st Lagrange resolvent $y = (x + \zeta^{-1}\sigma(x) + \zeta^{-2}\sigma^2(x))/3$ is equal to Y(t, x)where

$$Y(t,X) = ((2\zeta+1)X^2 - ((2\zeta+1)t + (\zeta-1))X - (\zeta+1)t - 4\zeta - 2)/3 \in \mathbb{Q}(t,\zeta)[X]$$

and ζ is a primitive 3rd root of unity in $\overline{\mathbb{Q}}$. Proposition 2.4 implies

$$g(t) = \operatorname{Res}_X(f_0(t, X), Y(t, X))$$

= $(t^3 + (3\zeta + 6)t^2 + (9\zeta + 18)t + (27\zeta + 27))/27$
= $(t - 3\zeta)(t + 3\zeta + 3)^2/27.$

Lemma 4.3. We have

$$L_0(\zeta) = \operatorname{Spl}_{\mathbb{Q}(t,\zeta)}(Y^3 - \frac{t - 3\zeta}{t + 3\zeta + 3}).$$

Let us denote $(t - 3\zeta)(t + 3\zeta + 3) = t^2 + 3t + 9$ by $d_0(t)$. For a prime number $p \neq 3$ we define $U_{0,p}(\mathbb{Q}) = \{a \in \mathbb{Q} | v_p(a) < 0 \text{ or } v_p(d_0(a)) \equiv 0 \pmod{3}\}$. The set $U_{0,3}(\mathbb{Q})$ is defined to be $U_{0,3}(\mathbb{Q}) = \{a \in \mathbb{Q} | v_3(a + 3/2) \neq 1, 2\}$. The following lemma was shown in [11], which is also seen in the same way as for the proof of Proposition 4.11 below.

Lemma 4.4 (Komatsu [11]). For a rational number $a \in \mathbb{Q}$ the conductor $\operatorname{cond}(L)$ of the extension $L = \operatorname{Spl}_{\mathbb{Q}} f_0(a, X)$ is equal to $\prod_p p^{r_p}$ where

$$r_p = \begin{cases} 1 & \text{if } p \neq 3 \text{ and } a \notin U_{0,p}, \\ 2 & \text{if } p = 3 \text{ and } a \notin U_{0,3}, \\ 0 & \text{otherwise.} \end{cases}$$

REMARK 4.5. For a cyclic extension L/K of prime degree l we have a relation $\operatorname{cond}(L/K)^{l-1} = \operatorname{disc}(L/K)$ between the conductor $\operatorname{cond}(L/K)$ and the discriminant $\operatorname{disc}(L/K)$ of L/K (cf. [19]).

REMARK 4.6. It is well-known that $f_0(t, X)$ is a generic \mathcal{C}_3 -polynomial over \mathbb{Q} (cf. [20]).

In the same way as for $f_0(t, X)$ one can calculate the invariants for cubic polynomials

$$\begin{aligned} f_1(t,X) &= X^3 - (t^3 - 2t^2 + 3t - 3)X^2 - t^2X - 1, \\ f_2(t,X) &= X^3 + 3(3t^2 - 3t + 2)X^2 + 3X - 1, \\ f_3(t,X) &= X^3 - t(t^2 + t + 3)(t^2 + 2)X^2 - (t^3 + 2t^2 + 3t + 3)X - 1, \\ f_4(t,X) &= X^3 + (t^8 + 2t^6 - 3t^5 + 3t^4 - 4t^3 + 5t^2 - 3t + 3)X^2 - t^2(t^3 - 2)X - 1. \end{aligned}$$

The $f_1(t, X)$ was given by Lecacheux [12] and the latters $f_i(t, X)$ for i = 2, 3 and 4 were obtained by Kishi [10]. The discriminants $\operatorname{disc} f_i(t, X)$ of the polynomials are

$$\begin{aligned} \operatorname{disc}_X f_1(t, X) &= (t-1)^2 (t^2+3)^2 (t^2-3t+3)^2, \\ \operatorname{disc}_X f_2(t, X) &= 3^6 (2t-1)^2 (t^2-t+1)^2, \\ \operatorname{disc}_X f_3(t, X) &= (t^2+1)^2 (t^2+3)^2 (t^4+t^3+4t^2+3)^2, \\ \operatorname{disc}_X f_4(t, X) &= (t^2-t+1)^2 (t^3+t-1)^2 (t^4-t^3+t^2-3t+3)^2 \\ &\times (t^4+2t^3+4t^2+3t+3)^2. \end{aligned}$$

For i = 1, 2, 3 and 4 let us denote $\text{Spl}_{\mathbb{Q}(t)} f_i(t, X)$ by L_i , respectively.

Proposition 4.7. We have

$$\begin{split} L_1(\zeta) &= \operatorname{Spl}_{\mathbb{Q}(t,\zeta)} \left(Y^3 - \frac{(t-2\zeta-1)(t-\zeta-2)}{(t+2\zeta+1)(t+\zeta-1)} \right), \\ L_2(\zeta) &= \operatorname{Spl}_{\mathbb{Q}(t,\zeta)} \left(Y^3 - \frac{t-\zeta-1}{t+\zeta} \right), \\ L_3(\zeta) &= \operatorname{Spl}_{\mathbb{Q}(t,\zeta)} \left(Y^3 - \frac{(t-2\zeta-1)(t^2-\zeta t+\zeta+2)}{(t+2\zeta+1)(t^2+(\zeta+1)t-\zeta+1)} \right), \\ L_4(\zeta) &= \operatorname{Spl}_{\mathbb{Q}(t,\zeta)} \left(Y^3 - \frac{(t-\zeta-1)(t^2+\zeta t-2\zeta-1)(t^2+t-\zeta+1)}{(t+\zeta)(t^2-(\zeta+1)t+2\zeta+1)(t^2+t+\zeta+2)} \right). \end{split}$$

Corollary 4.8 (Kishi [10]). We have $\operatorname{Spl}_{\mathbb{Q}(t)}f_2(t,X) = \operatorname{Spl}_{\mathbb{Q}(t)}f_0(-3t,X)$.

Proof. Proposition 4.7 implies that $\operatorname{Spl}_{\mathbb{Q}(t,\zeta)} f_2(t,X) = \operatorname{Spl}_{\mathbb{Q}(t,\zeta)} f_0(-3t,X)$. Here two fields $\operatorname{Spl}_{\mathbb{Q}(t,\zeta)} f_2(t,X)$ and $\operatorname{Spl}_{\mathbb{Q}(t,\zeta)} f_0(-3t,X)$ are $\mathcal{C}_3 \times \mathcal{C}_2$ -extensions of $\mathbb{Q}(t)$. Thus the two fields have unique subextensions M of $\mathbb{Q}(t)$ with $[M : \mathbb{Q}(t)] = 3$, which are equal to $\operatorname{Spl}_{\mathbb{Q}(t)} f_2(t,X)$ and $\operatorname{Spl}_{\mathbb{Q}(t)} f_0(-3t,X)$, respectively. Thus we have $\operatorname{Spl}_{\mathbb{Q}(t)} f_2(t,X) = \operatorname{Spl}_{\mathbb{Q}(t)} f_0(-3t,X)$.

By Propositions 2.6 and 4.7 we have

Corollary 4.9. The polynomials $f_1(t, X)$, $f_3(t, X)$ and $f_4(t, X)$ are not potentially generic over \mathbb{Q} . Proof of Proposition 4.7. For i = 1, 2, 3 and 4 let x_i be solutions of $f_i(t, X) = 0$ in L_i , respectively. Then one can check that the following elements σ_i generate the Galois groups $\operatorname{Gal}(L_i/\mathbb{Q}(t)) \simeq C_3$ and can calculate the the cubes $\lambda_i(t) \in \mathbb{Q}(t, \zeta)$ of 1st Lagrange resolvents by using Lemma 2.4, respectively.

$$\begin{split} \sigma_1(x_1) &= -(t^2 - t + 1)/(t - 1)x_1^2 + (t^4 - 2t^3 + 4t^2 - 4t + 2)x_1 \\ &+ (t^4 - 2t^3 + 3t^2 - 3t + 2)/(t - 1), \\ \lambda_1(t) &= (t - 2\zeta - 1)(t + 2\zeta + 1)^2(t - \zeta - 2)(t + \zeta - 1)^2(t - \zeta - 1)^3/27, \\ \sigma_2(x_2) &= -(3t^2 - 3t + 1)/(2t - 1)x_2^2 \\ &- (27t^4 - 54t^3 + 54t^2 - 26t + 5)/(2t - 1)x_2 \\ &- (9t^3 - 9t^2 + 6t - 2)/(2t - 1), \\ \lambda_2(t) &= -(t - \zeta - 1)(t + \zeta)^2(3t - \zeta - 2)^3, \\ \sigma_3(x_3) &= -(t^4 + t^3 + 3t^2 + t + 1)/(t^2 + 1)x_3^2 \\ &+ t(t^8 + 2t^7 + 9t^6 + 11t^5 + 25t^4 + 18t^3 + 25t^2 + 8t + 7)/(t^2 + 1)x_3 \\ &+ (t^7 + 2t^6 + 7t^5 + 8t^4 + 13t^3 + 8t^2 + 6t + 2)/(t^2 + 1), \\ \lambda_3(t) &= (t - 2\zeta - 1)(t + 2\zeta + 1)^2 \\ &\times (t^2 - \zeta t + \zeta + 2)(t^2 + (\zeta + 1)t - \zeta + 1)^2(t^2 - \zeta t + 1)^3/27, \\ \sigma_4(x_4) &= -(t^6 + t^4 - 2t^3 + t^2 - t + 1)/(t^3 + t - 1)x_4^2 \\ &- (t^{14} + 3t^{12} - 5t^{11} + 6t^{10} - 12t^9 + 17t^8 - 18t^7 \\ &+ 24t^6 - 23t^5 + 21t^4 - 17t^3 + 11t^2 - 6t + 2)/(t^3 + t - 1)x_4 \\ &- (t^2 + 1)(t^7 + t^5 - 3t^4 + 2t^3 - t^2 + 3t - 2)/(t^3 + t - 1), \\ \lambda_4(t) &= -(t - \zeta - 1)(t + \zeta)^2(t^2 + \zeta t - 2\zeta - 1)(t^2 - (\zeta + 1)t + 2\zeta + 1)^2 \\ &\times (t^2 + t - \zeta + 1)(t^2 + t + \zeta + 2)^2(t^3 - \zeta t - 1)^3/27. \end{split}$$

Thus the equations of the assertion hold.

REMARK 4.10. On $f_1(t, X)$ Washington [26] gave a generator ρ of $\operatorname{Gal}(L_1/\mathbb{Q}(t))$ satisfying $\rho(x) = -(x+1)/((t^2-t+1)x+t)$. In fact, one has $\rho = \sigma_1^2$.

For i = 1, 2, 3 and 4 let $\lambda_i(t) \in \mathbb{Q}(\zeta)[t]$ be the polynomials as in the proof of Proposition 4.7. For j = 1, 2 and 3 let $d_{i,j}(t)$ be the products of all the monic prime divisors whose multiplicities in $\lambda_i(t)$ are equal to j, respectively, that is,

$$\begin{aligned} d_{1,1}(t) &= (t - 2\zeta - 1)(t - \zeta - 2), \quad d_{1,2}(t) = (t + 2\zeta + 1)(t + \zeta - 1), \\ d_{2,1}(t) &= t - \zeta - 1, \qquad d_{2,2}(t) = t + \zeta, \\ d_{3,1}(t) &= (t - 2\zeta - 1)(t^2 - \zeta t + \zeta + 2), \\ d_{3,2}(t) &= (t + 2\zeta + 1)(t^2 + (\zeta + 1)t - \zeta + 1), \\ d_{4,1}(t) &= (t - \zeta - 1)(t^2 + \zeta t - 2\zeta - 1)(t^2 + t - \zeta + 1), \\ d_{4,2}(t) &= (t + \zeta)(t^2 - (\zeta + 1)t + 2\zeta + 1)(t^2 + t + \zeta + 2). \end{aligned}$$

Note that $\tau(d_{i,1}(t)) = d_{i,2}(t)$ for $\tau \in \operatorname{Gal}(\mathbb{Q}(t,\zeta)/\mathbb{Q}(t))$ with $\tau(\zeta) = \zeta^2$. We denote by $d_i(t) \in \mathbb{Q}[t]$ the products $d_{i,1}(t)d_{i,2}(t)$. Then one has

$$d_{1}(t) = (t^{2} + 3)(t^{2} - 3t + 3),$$

$$d_{2}(t) = t^{2} - t + 1,$$

$$d_{3}(t) = (t^{2} + 3)(t^{4} + t^{3} + 4t^{2} + 3),$$

$$d_{4}(t) = (t^{2} - t + 1)(t^{4} - t^{3} + t^{2} - 3t + 3)(t^{4} + 2t^{3} + 4t^{2} + 3t + 3).$$

For an odd prime number p > 3 we define

$$U_{i,p}(\mathbb{Q}) = \{ a \in \mathbb{Q} | v_p(a) < 0 \text{ or } v_p(d_i(a)) \equiv 0 \pmod{3} \},\$$

and put $U_{i,2}(\mathbb{Q}) = \mathbb{Q}$ for the case p = 2. Here v_p is the *p*-adic valuation. The sets $U_{i,3}(\mathbb{Q})$ are defined to be $U_{i,3}(\mathbb{Q}) = \{a \in \mathbb{Q} | v_3(\mu_i(a)) \ge 1\}$ where $\mu_i(t) \in \mathbb{Q}(t)$ are rational functions such that

$$\mu_i(t) = \frac{(d_{i,1}(t) + d_{i,2}(t))(d_{i,1}(t) - d_{i,2}(t))}{(\zeta^{-1} - \zeta)d_i(t)},$$

respectively.

Proposition 4.11. For a rational number $a \in \mathbb{Q}$, the conductor cond(L) of the extension $L = \text{Spl}_{\mathbb{Q}} f_i(a, X)$ is equal to $\prod_p p^{r_p}$ where

$$r_p = \begin{cases} 1 & \text{if } p \neq 3 \text{ and } a \notin U_{i,p}, \\ 2 & \text{if } p = 3 \text{ and } a \notin U_{i,3}, \\ 0 & \text{otherwise.} \end{cases}$$

For i = 1, 2, 3 and 4 let $h_i \in \mathbb{Q}(\zeta)$ be the squares of the resultants of $d_{i,1}(t)$ and $d_{i,2}(t)$, that is, $h_i = \operatorname{Res}_t(d_{i,1}(t), d_{i,2}(t))^2$. Note that $h_i \in \mathbb{Q}$. In fact, $\tau(h_i) = \operatorname{Res}_t(d_{i,2}(t), d_{i,1}(t))^2 = \operatorname{Res}_t(d_{i,1}(t), d_{i,2}(t))^2 = h_i$. By the direct calculation one sees

Lemma 4.12. We have $h_1 = 2^2 \cdot 3^6$, $h_2 = -3$, $h_3 = -2^2 \cdot 3^9$ and $h_4 = -3^{19}$.

Proof of Proposition 4.11. For a rational number $a \in \mathbb{Q}$ let L denote the algebraic number field $\operatorname{Spl}_{\mathbb{Q}} f_i(a, X)$. Let p be a prime number and \mathfrak{p} a prime ideal of $\mathbb{Q}(\zeta)$ above p. It follows from the ramification-conductor theorem that p ramifies in L/\mathbb{Q} if and only if $r_p = v_p(\operatorname{cond}(L)) \geq 1$. Class field theory implies that when L/\mathbb{Q} is ramified at p, we have $r_p = 2$ if p = 3 and $r_p = 1$ otherwise. Since the degrees of two cyclic extensions $\mathbb{Q}(\zeta)$ and L of \mathbb{Q} are relatively prime, p ramifies in L/\mathbb{Q} if and only if so does \mathfrak{p} in $L(\zeta)/\mathbb{Q}(\zeta)$. Let us show that $a \in U_{i,p}$ if and only if \mathfrak{p} does not ramify in $L(\zeta)/\mathbb{Q}(\zeta)$. Now denote the ratio $d_{i,1}(a)/d_{i,2}(a)$ by γ . We first note that 2 does not ramify in any cyclic cubic field. Let us assume $p \geq 5$. If $v_p(a) < 0$, then $v_p(d_{i,1}(a)) = v_p(d_{i,2}(a)) < 0$ and $v_p(\gamma) = 0$ where v_p is the **p**-adic valuation. Thus it follows from Lemma 4.1 (2) that $L(\zeta)/\mathbb{Q}(\zeta)$ is unramified at **p**. Since $v_p(h_i) = 0$, the equation $v_p(d_i(a)) \equiv 0 \pmod{3}$ is equivalent to $v_p(\gamma) \equiv 0 \pmod{3}$ under the condition $v_p(a) \geq 0$. Lemma 4.1 (1) and (2) imply that $L(\zeta)/\mathbb{Q}(\zeta)$ is unramified at **p** if and only if $v_p(d_i(a)) \equiv 0 \pmod{3}$. Next consider the case p = 3. For $\tau(d_{i,1}(a)) = d_{i,2}(a)$ one has $v_p(\gamma) = 0$. Corollary 4.2 implies that $L(\zeta)/\mathbb{Q}(\zeta)$ is unramified at **p** if and only if $v_p(\gamma^2 - 1) \geq 3$. Here it holds that $v_p(\gamma^2 - 1) = v_p(\gamma - \gamma^{-1}) = v_p(\mu_i(a)) + 1 = 2v_3(\mu_i(a)) + 1$. Hence $L(\zeta)/\mathbb{Q}(\zeta)$ is unramified at **p** if and only if $v_3(\mu_i(a)) \geq 1$. \Box In the same way as above Corollary 4.2 shows

Corollary 4.13. For a rational number $a \in \mathbb{Q}$ the prime number 3 ramifies, remains prime and splits completely in the extension $\text{Spl}_{\mathbb{Q}}f_i(a, X)/\mathbb{Q}$ provided the valuation $v_3(\mu_i(a))$ is equal to 0, 1 and is greater than 1, respectively.

Lemma 4.14. We have

$$\begin{split} \mu_1(t) &= \frac{3(t-1)(2t^2-3t-3)}{(t^2+3)(t^2-3t+3)},\\ \mu_2(t) &= \frac{2t-1}{t^2-t+1},\\ \mu_3(t) &= \frac{3(t^2+1)(2t^3+t^2+3)}{(t^2+3)(t^4+t^3+4t^2+3)},\\ \mu_4(t) &= \frac{3(t^3+t-1)(2t^5+3t^3-4t^2-3t-3)}{(t^2-t+1)(t^4-t^3+t^2-3t+3)(t^4+2t^3+4t^2+3t+3)} \end{split}$$

and

$$U_{1,3}(\mathbb{Q}) = \{ a \in \mathbb{Q} | v_3(a) \le 0 \}, U_{2,3}(\mathbb{Q}) = \{ a \in \mathbb{Q} | v_3(a) \le -1 \text{ or } v_3(a-5) \ge 2 \}.$$

The set $U_{3,3}(\mathbb{Q})$ is equal to the set of the rational numbers $a \in \mathbb{Q}$ satisfying one of the disjoint three conditions (i) $v_3(a) \leq -1$, (ii) $v_3(a-2) \geq 1$ and (iii) $v_3(a-16) \geq 3$. The set $U_{4,3}(\mathbb{Q})$ is equal to the set of the rational numbers $a \in \mathbb{Q}$ satisfying one of the disjoint four conditions (iv) $v_3(a) \leq -1$, (v) $v_3(a-1) \geq 1$, (vi) $v_3(a-2) \geq 2$ and (vii) $v_3(a-14) \geq 3$.

Proof. One can directly calculate the invariants $\mu_i(t)$ for i = 1, 2, 3 and 4. If $v_3(a) \leq 0$, then $v_3(\mu_1(a)) \geq 1$. When $v_3(a) \geq 1$, one has $v_3(\mu_1(a)) = 0$. Thus

we have $U_{1,3}(\mathbb{Q}) = \{a \in \mathbb{Q} | v_3(a) \leq 0\}$. If $v_3(a) \leq -1$, then $v_3(\mu_2(a)) \geq 1$. When $v_3(a) \geq 1$ or $v_3(a-1) \geq 1$, it holds that $v_3(\mu_2(a)) = 0$. Here one has $\mu_2(2+3t_1) = (2t_1+1)/(3t_1^2+3t_1+1)$. Thus $v_3(a-5) \geq 2$ (resp. $v_3(a-5) = 1$) implies $v_3(\mu_2(a)) \geq 1$ (resp. $v_3(\mu_2(a)) = 0$). This shows that $U_{2,3}(\mathbb{Q}) = \{a \in \mathbb{Q} | v_3(a) \leq -1 \text{ or } v_3(a-5) \geq 2\}$.

If $v_3(a) \leq -1$, then $v_3(\mu_3(a)) \geq 2$. Here one sees

$$\mu_3(1+3t_1) = \frac{(9t_1^2+6t_1+2)(18t_1^3+21t_1^2+8t_1+2)}{(9t_1^2+6t_1+4)(9t_1^4+15t_1^3+13t_1^2+5t_1+1)},$$

which means that $v_3(\mu_3(a)) = 0$ provided $v_3(a-7) = 1$. By the equation

$$\mu_3(7+9t_2) = \frac{(81t_2^2 + 126t_2 + 50)(162t_2^3 + 387t_2^2 + 308t_2 + 82)}{(81t_2^2 + 126t_2 + 52)(243t_2^4 + 783t_2^3 + 957t_2^2 + 525t_2 + 109)},$$

one sees that $v_3(\mu_3(a)) = 0$ if $v_3(a - 16) = 2$. When $v_3(a - 16) \ge 3$, we have $v_3(\mu_3(a)) \ge 1$. For the case $v_3(a - 2) \ge 1$, it holds that $v_3(\mu_3(a)) = 1$. If $v_3(a) \ge 1$, then $v_3(\mu_3(a)) = 0$. Thus we see the assertion for the $U_{3,3}(\mathbb{Q})$.

If $v_3(a) \leq -1$, then $v_3(\mu_4(a)) \geq 3$. When $v_3(a-1) \geq 1$, we have $v_3(\mu_4(a)) = 1$.

By the direct calculation one sees

$$\begin{split} \mu_4(2+3t_1) &= (9t_1^3+18t_1^2+13t_1+3)(54t_1^5+180t_1^4+249t_1^3+174t_1^2+59t_1+7) \\ &\times (3t_1^2+3t_1+1)^{-1}(9t_1^4+21t_1^3+19t_1^2+7t_1+1)^{-1} \\ &\times (27t_1^4+90t_1^3+120t_1^2+75t_1+19)^{-1}, \\ \mu_4(5+9t_2) &= (243t_2^3+405t_2^2+228t_2+43) \\ &\times (4374t_2^5+12150t_2^4+13581t_2^3+7623t_2^2+2144t_2+241) \\ &\times (27t_2^2+27t_2+7)^{-1} \\ &\times (243t_2^4+513t_2^3+408t_2^2+144t_2+19)^{-1} \\ &\times (2187t_2^4+5346t_2^3+4968t_2^2+2079t+331)^{-1}. \end{split}$$

If $v_3(a-2) \ge 2$, then $v_3(\mu_4(a)) \ge 1$. When $v_3(a-8) \ge 2$, we have $v_3(\mu_4(a)) = 0$. For the case $v_3(a-14) \ge 3$ (resp. $v_3(a-14) = 2$), one has $v_3(\mu_4(a)) \ge 1$ (resp. $v_3(\mu_4(a)) = 0$). When $v_3(a) \ge 1$, it holds that $v_3(\mu_4(a)) = 0$. Hence we have verified the assertion for the $U_{4,3}(\mathbb{Q})$.

§ 5. Two examples of quintic polynomials

Let us consider a quintic polynomial

$$f_5(t, X) = X^5 + t^2 X^4 - 2(t^3 + 3t^2 + 5t + 5)X^3 + (t^4 + 5t^3 + 11t^2 + 15t + 5)X^2 + (t^3 + 4t^2 + 10t + 10)X + 1,$$

which is called the quintic polynomial of Lehmer type [14]. The discriminant of the polynomial $f_5(t, X)$ is equal to $(t^3 + 5t^2 + 10t + 7)^2(t^4 + 5t^3 + 15t^2 + 25t + 25)^4$.

Let us denote $\operatorname{Spl}_{\mathbb{Q}(t)} f_5(t, X)$ by L_5 and fix a solution $x_5 \in L_5$ of $f_5(t, X) = 0$. Note that $[\mathbb{Q}(t, x_5) : \mathbb{Q}(t)] = 5$. In fact, a specialized polynomial $f_5(0, X - 1) = X^5 - 5X^4 + 25X^2 - 25X + 5$ is Eisenstein at the prime number 5. This means that $f_5(t, X)$ is irreducible over $\mathbb{Q}(t)$. It can be checked by a calculator that

$$\begin{aligned} x' &= ((t+1)x_5^4 + (t^3 + 2t^2 + 3t + 3)x_5^3 - (t+1)(t+2)(t^2 + t + 4)x_5^2 \\ &- (t^4 + 7t^3 + 19t^2 + 29t + 19)x_5 + (t+1)(t^3 + 5t^2 + 11t + 9))/\delta_5(t) \end{aligned}$$

is a solution of $f_5(t, X) = 0$ where $\delta_5(t) = t^3 + 5t^2 + 10t + 7$. It follows from $[\mathbb{Q}(t, x_5) : \mathbb{Q}(t)] = 5$ that $x' \neq x_5$. Thus there exists an element $\sigma_5 \in \text{Gal}(L_5/\mathbb{Q}(t))$ such that $\sigma_5(x_5) = x'$. By the direct computation with a calculator it is seen that

$$\begin{split} \sigma_5(x_5) &= ((t+1)x_5^4 + (t^3 + 2t^2 + 3t + 3)x_5^3 - (t+1)(t+2)(t^2 + t + 4)x_5^2 \\ &-(t^4 + 7t^3 + 19t^2 + 29t + 19)x_5 + (t+1)(t^3 + 5t^2 + 11t + 9))/\delta_5(t), \\ \sigma_5^2(x_5) &= (-(t+1)(t+2)x_5^4 - (t+1)^2(t^2 + t - 1)x_5^3 \\ &+(2t^5 + 12t^4 + 33t^3 + 54t^2 + 53t + 23)x_5^2 \\ &-(t+1)(t+2)(t^4 + 5t^3 + 12t^2 + 16 + 9)x_5 \\ &-(t^5 + 7t^4 + 24t^3 + 47t^2 + 52t + 25))/\delta_5(t), \\ \sigma_5^3(x_5) &= (-(2t+3)x_5^4 - (2t^3 + 4t^2 + 3t + 2)x_5^3 \\ &+(3t^4 + 14t^3 + 31t^2 + 41t + 24)x_5^2 \\ &-(t+3)(t^4 + 4t^3 + 9t^2 + 9t + 2)x_5 - (t+2)(2t+3))/\delta_5(t), \\ \sigma_5^4(x_5) &= ((t+2)^2x_5^4 + (t+1)(t+2)(t^2 + t - 1)x_5^3 \\ &-(2t^5 + 14t^4 + 43t^3 + 76t^2 + 80t + 39)x_5^2 \\ &+(t+1)(t^5 + 8t^4 + 29t^3 + 60t^2 + 71t + 36)x_5 \\ &+(t+2)(t^3 + 6t^2 + 14t + 11))/\delta_5(t) \end{split}$$

and $\sigma_5^5(x_5) = x_5$. Thus it holds that $L_5 = \mathbb{Q}(t, x_5)$ and $\operatorname{Gal}(L_5/\mathbb{Q}(t)) = \langle \sigma_5 \rangle \simeq \mathcal{C}_5$. Using Lemma 2.4 it is calculated that 1st Lagrange resolvent y_5 of x_5 for $L_5/\mathbb{Q}(t)$ satisfies

$$(5y_5)^5 = -t^{10} + (5\zeta^3 + 5\zeta - 10)t^9 + (70\zeta^3 + 10\zeta^2 + 55\zeta - 35)t^8 + (450\zeta^3 + 125\zeta^2 + 300\zeta)t^7 + (1775\zeta^3 + 725\zeta^2 + 1025\zeta + 475)t^6 + (4750\zeta^3 + 2625\zeta^2 + 2375\zeta + 2125)t^5 + (8875\zeta^3 + 6500\zeta^2 + 3750\zeta + 5250)t^4 + (11250\zeta^3 + 11250\zeta^2 + 3750\zeta + 8125)t^3 + (8750\zeta^3 + 13125\zeta^2 + 1875\zeta + 7500)t^2 + (3125\zeta^3 + 9375\zeta^2 + 3125)t + 3125\zeta^2 = -(t - \alpha_1)(t - \alpha_2)^3(t - \alpha_3)^2(t - \alpha_4)^4$$

where ζ is a primitive 5th root of unity in $\overline{\mathbb{Q}}$ and

$$\alpha_1 = -\zeta^3 - 2\zeta - 2, \qquad \alpha_2 = -2\zeta^2 - \zeta - 2, \alpha_3 = -\zeta^3 + \zeta^2 + \zeta - 1, \qquad \alpha_4 = 2\zeta^3 + \zeta^2 + 2\zeta.$$

Here α_j are zeros of $t^4 + 5t^3 + 15t^2 + 25t + 25 = \prod_{j=1}^4 (t - \alpha_j)$ and $\tau_j(\alpha_1) = \alpha_j$ where $\tau_j \in \operatorname{Gal}(\mathbb{Q}(t,\zeta))/\mathbb{Q}(t))$ such that $\tau_j(\zeta) = \zeta^j$. We denote the rational function $(t - \alpha_1)(t - \alpha_2)^3(t - \alpha_3)^2(t - \alpha_4)^4 \in \mathbb{Q}(t,\zeta)$ by $\lambda_5(t)$. Corollary 2.2 and Proposition 2.6 imply

Proposition 5.1. We have $L_5(\zeta) = \operatorname{Spl}_{\mathbb{Q}(t,\zeta)}(Y^5 - \lambda_5(t))$. In particular, $f_5(t,X)$ is not potentially generic over \mathbb{Q} .

REMARK 5.2. Schoof and Washington [18] showed that $L_5 = \mathbb{Q}(t, x_5)$ is a cyclic quintic extension of $\mathbb{Q}(t)$ whose Galois group $\operatorname{Gal}(L_5/\mathbb{Q}(t))$ is generated by

$$\rho(x_5) = \frac{-x_5^2 + tx_5 + t + 2}{(t+2)x_5 + 1}$$

In fact, $\rho = \sigma_5^4 \in \text{Gal}(L_5/\mathbb{Q}(t))$. Spearman and Williams [24] also gave a generator for $\text{Gal}(L_5/\mathbb{Q}(t))$ whose form is the same as that of σ_5^4 and obtained the same equations on $\sigma_5^j(x_5)$ as above.

Thaine [25] gave a quintic polynomial $f_6(t, X)$ such that

$$f_6(t,X) = X^5 + (2t^2 + 5t + 10)X^4 + (t^4 + 5t^3 + 17t^2 + 25t + 25)X^3 + (t^4 + 3t^3 + 7t^2 + 5t + 5)X^2 - (t^3 + 3t^2 + 5t + 5)X - 1.$$

The discriminant of the polynomial $f_6(t, X)$ is equal to

$$(t^4 + 4t^3 + 10t^2 + 15t + 7)^2(t^4 + 5t^3 + 15t^2 + 25t + 25)^4.$$

Let us denote $\operatorname{Spl}_{\mathbb{Q}(t)} f_6(t, X)$ by L_6 and fix a solution $x_6 \in L_6$ of $f_6(t, X) = 0$. In the same way as that of the case $f_5(t, X)$, one can see that $\operatorname{Gal}(L_6/\mathbb{Q}(t)) \simeq C_5$ is generated by σ_6 such that

$$\sigma_{6}(x_{6}) = ((t+3)x_{6}^{4} + (2t^{3} + 10t^{2} + 23t + 28)x_{6}^{3} + (t^{5} + 6t^{4} + 23t^{3} + 52t^{2} + 68t + 54)x_{6}^{2} - (t^{6} + 6t^{5} + 23t^{4} + 56t^{3} + 92t^{2} + 99t + 42)x_{6} - (t^{6} + 6t^{5} + 22t^{4} + 52t^{3} + 80t^{2} + 80t + 36))/\delta_{6}(t)$$

where $\delta_6(t) = t^4 + 4t^3 + 10t^2 + 15t + 7$. The 1st Lagrange resolvent y_6 of x_6 for $L_6/\mathbb{Q}(t)$ satisfies

$$(5y_6)^5 = \varepsilon^5 (t - \alpha_1)^2 (t - \alpha_2) (t - \alpha_3)^4 (t - \alpha_4)^3$$

where $\varepsilon = \zeta^3 + \zeta^2 + 1 \in \mathcal{O}_{\mathbb{Q}(\zeta)}^{\times}$ and the elements α_j are the same as for $f_5(t, X)$.

Proposition 5.3. We have $L_5 = L_6$.

Proof. By the above argument one has $y_5^2/y_6 \in \mathbb{Q}(t,\zeta)^5$. Corollary 2.2 implies that $L_5(\zeta) = L_6(\zeta)$ from Kummer theory. The Galois groups of the extensions $L_i(\zeta)/\mathbb{Q}(t)$ are isomorphic to $\mathcal{C}_5 \times \mathcal{C}_4$, respectively. Each $\mathcal{C}_5 \times \mathcal{C}_4$ -extension $L_i(\zeta)/\mathbb{Q}(t)$ has a unique quintic extension L_i of $\mathbb{Q}(t)$ for i = 5 and 6. Thus we see $L_5 = L_6$. More precisely than Proposition 5.3 one can obtain an explicit relation between the solutions of $f_5(t, X) = 0$ and $f_6(t, X) = 0$. Let us define polynomials $\theta(X)$ and $\widehat{\theta}(X) \in \mathbb{Q}(t)[X]$ by

$$\begin{split} \theta(X) &= ((t+1)X^4 + (t^3 + 2t^2 + 3t + 3)X^3 \\ &- (t+1)(t+2)(t^2 + t + 4)X^2 \\ &- (t+3)(t^3 + 3t^2 + 5t + 4)X - (t^3 + 4t^2 + 7t + 5))/\delta_5(t), \\ \widehat{\theta}(X) &= ((t^2 + 2t + 2)X^4 + (2t^4 + 9t^3 + 24t^2 + 32t + 21)X^3 \\ &+ (t^6 + 7t^5 + 29t^4 + 72t^3 + 118t^2 + 119t + 57)X^2 \\ &+ (t^3 + 3t^2 + 6t + 3)(t^3 + 3t^2 + 6t + 7)X - (t + 3))/\delta_6(t). \end{split}$$

Proposition 5.4. We have

$$f_5(t,X) = \prod_{m=0}^4 (X - \hat{\theta}(\sigma_6^m(x_6))), \quad f_6(t,X) = \prod_{m=0}^4 (X - \theta(\sigma_5^m(x_5))),$$

 $\widehat{\theta} \circ \theta(x_5) = x_5$ and $\theta \circ \widehat{\theta}(x_6) = x_6$. In the Galois extension $L_5 = L_6$ of $\mathbb{Q}(t)$, the action of σ_5 is equivalent to that of σ_6^2 .

Proof. Let $\tilde{\tau}_j \in \operatorname{Gal}(L_5L_6(\zeta)/\mathbb{Q}(t))$ be an extension of $\tau_j \in \operatorname{Gal}(\mathbb{Q}(t,\zeta)/\mathbb{Q}(t))$ such that $\tilde{\tau}_j(\zeta) = \tau_j(\zeta) = \zeta^j$ and $\tilde{\tau}_j(x_i) = x_i$ for i = 5 and 6. By the argument above one has that $y_6^5 = -\varepsilon^5 \tilde{\tau}_2(y_5)^5$. This means that $y_6 = -\zeta^b \varepsilon \tilde{\tau}_2(y_5)$ for an integer $b \in \mathbb{Z}$. Let $\tilde{\sigma}_i \in \operatorname{Gal}(L_i(\zeta)/\mathbb{Q}(t))$ be an extension of $\sigma_i \in \operatorname{Gal}(L_i/\mathbb{Q}(t))$ such that $\tilde{\sigma}_i(x_i) = \sigma_i(x_i)$ and $\tilde{\sigma}_i(\zeta) = \zeta$ for i = 5 and 6, respectively. Then it holds that $\tilde{\sigma}_i \tilde{\tau}_j = \tilde{\tau}_j \tilde{\sigma}_i$ as the actions on $L_i(\zeta)$. Lemma 2.1 implies that $\tilde{\sigma}_6(y_6) = \zeta y_6$. Thus one has $\tilde{\sigma}_6^{-b+1}(y_6) = -\zeta \varepsilon \tilde{\tau}_2(y_5)$. Let us put $\eta_5 = -\zeta \varepsilon \tilde{\tau}_2(y_5)$ and $\eta_6 = \tilde{\sigma}_6^{-b+1}(y_6)$. It follows from the definition that $\sum_{j=1}^4 \tilde{\tau}_j(y_i) = 4x_i/5 - \sum_{m=1}^4 \sigma_i^m(x_i)/5 = x_i - T_i(x_i)/5$ where $T_i(x_i) = \sum_{m=0}^4 \sigma_i^m(x_i) \in \mathbb{Q}(t)$. Since $\tilde{\tau}_j \tilde{\sigma}_i(y_i) = \tilde{\sigma}_i \tilde{\tau}_j(y_i)$, it satisfies that $\sum_{j=1}^4 \tilde{\tau}_j(\tilde{\sigma}_i^m(y_i)) = \sigma_i^m(x_i) - T_i(x_i)/5$

for an integer $m \in \mathbb{Z}$. This shows that $\sum_{j=1}^{4} \widetilde{\tau_j}(\eta_6) = \sigma_6^{-b+1}(x_6) - T_6(x_6)/5$. Here it is seen that $\eta_5 = \widetilde{\tau_2}(-\zeta^3(\zeta^4 + \zeta + 1)y_5) = \widetilde{\tau_2}((\zeta + 1)y_5) = \widetilde{\tau_2}(y_5 + \widetilde{\sigma_5}(y_5))$. Thus we have $\sum_{j=1}^{4} \widetilde{\tau_j}(\eta_5) = x_5 + \sigma_5(x_5) - 2T_5(x_5)/5$. Hence the element $\widetilde{\sigma_6}^{-b+1}(x_6)$ is equal to $x_5 + \sigma_5(x_5) - 2T_5(x_5)/5 + T_6(x_6)/5 = \theta(x_5)$ where $T_5(x_5) = -t^2$ and $T_6(x_6) = -(2t^2 + 5t + 10)$. Since $\tilde{\sigma_6}^{-b+1}(x_6)$ is a solution of $f_6(t, X) = 0$, so is $\theta(x_5)$. Note that $f_6(t, X)$ and $\theta(X)$ are defined over $\mathbb{Q}(t)$. Thus $\sigma_5^m \theta(x_5) = \theta(\sigma_5^m(x_5))$ are also solutions of $f_6(t, X) = 0$. If $\sigma_5^{m_1} \theta(x_5) = \sigma_5^{m_2} \theta(x_5)$ for $0 \leq m_1 < m_2 \leq 4$, then $f_6(t, X)$ is reducible over $\mathbb{Q}(t)$, which is a contradiction. This means that $f_6(t, X) = \prod_{m=0}^4 (X - \theta(\sigma_5^m(x_5)))$ and $L_6 \subseteq L_5$. In the same way as above one can find $\hat{\theta}(X) \in \mathbb{Q}(t)[X]$ such that $f_5(t, X) = \prod_{m=0}^4 (X - \hat{\theta}(\sigma_6^m(x_6)))$ and $\hat{\theta} \circ \theta(x_5) = x_5$. Thus we prove $L_5 = L_6$. It satisfies that $\theta \circ \hat{\theta} \circ \theta(x_5) = \theta(x_5)$ and $\theta \circ \hat{\theta}(\sigma_6^{-b+1}(x_6)) = \sigma_6^{-b+1}(x_6)$. Since $\theta(X)$ and $\hat{\theta}(X)$ are defined over $\mathbb{Q}(t)$, we have $\theta \circ \hat{\theta}(x_6) = x_6$. Note that $\tilde{\sigma}_5^m(\eta_5) = -\zeta \varepsilon \tilde{\tau}_2(\tilde{\sigma}_5^m(y_5)) = -\zeta \varepsilon \tilde{\tau}_2(\zeta^m y_5) = -\zeta \varepsilon \zeta^{2m} \tilde{\tau}_2(y_5) = \zeta^{2m} \eta_5$. On the other hand, one has $\tilde{\sigma}_6^m(\eta_6) = \zeta^m \eta_6$. This means that $\sigma_5 = \sigma_6^2$ as the actions on $L_5 = L_6$.

REMARK 5.5. There exist five pairs $(\theta(X), \hat{\theta}(X))$ satisfying all of the equations in Proposition 5.4. We give a pair which is calculated by using $\sigma_5(x_5)$.

Let us denote $t^4 + 5t^3 + 15t^2 + 25t + 25 = \prod_{j=1}^4 (t - \alpha_j)$ by d(t). For an odd prime number p > 5 we define

$$U_p(\mathbb{Q}) = \{ a \in \mathbb{Q} | v_p(a) < 0 \text{ or } v_p(d(a)) \equiv 0 \pmod{5} \},\$$

and put $U_2(\mathbb{Q}) = U_3(\mathbb{Q}) = \mathbb{Q}$ for the cases p = 2 and 3, respectively. The set $U_5(\mathbb{Q})$ is defined to be $U_5(\mathbb{Q}) = \{a \in \mathbb{Q} | v_5(a) \le 0\}.$

Proposition 5.6 (Spearman-Williams [23]). For a rational number $a \in \mathbb{Q}$ the conductor of the extension $\operatorname{Spl}_{\mathbb{Q}}f_5(a, X) = \operatorname{Spl}_{\mathbb{Q}}f_6(a, X)$ is equal to $\prod_p p^{r_p}$ where

$$r_p = \begin{cases} 1 & \text{if } p \neq 5 \text{ and } a \notin U_p, \\ 2 & \text{if } p = 5 \text{ and } a \notin U_5, \\ 0 & \text{otherwise.} \end{cases}$$

Proof. In the same way as that in the proof of Proposition 4.11 one can show the assertion for the case $p \neq 5$. In fact, it is seen that $\operatorname{disc}_t d(t) = \prod_{1 \leq j_1 < j_2 \leq 4} (\alpha_{j_1} - \alpha_{j_2})^2 = 5^7$. Let us denote $(a - \alpha_1)(a - \alpha_2)^{-2}(a - \alpha_3)^2(a - \alpha_4)^{-1} \in \mathbb{Q}(\zeta)$ by γ . Then one has that $N_{\langle \tau_4 \rangle}(\gamma) = 1$ and $v_\mathfrak{p}(\gamma) = 0$ where τ_4 is an element of order 2 in $\operatorname{Gal}(\mathbb{Q}(\zeta)/\mathbb{Q})$ such that $\tau_4(\zeta) = \zeta^4$. Corollary 4.2 implies that $L(\zeta)/\mathbb{Q}(\zeta)$ is

unramified at $\mathbf{p} = (\zeta - 1)$ if and only if $v_{\mathbf{p}}(\gamma^2 - 1) \ge 5$. Now put $\mu = (\gamma - \gamma^{-1})/(\zeta - \zeta^{-1})$. Then it holds that $v_{\mathbf{p}}(\gamma^2 - 1) = v_{\mathbf{p}}(\gamma - \gamma^{-1}) = v_{\mathbf{p}}(\mu) + 1$. One can calculate $\mu \tau_2(\mu) = \widetilde{\mu} \in \mathbb{Q}$ where $\tau_2(\zeta) = \zeta^2$ and $\widetilde{\mu} = -\frac{5^2(a^4 + 6a^3 + 14a^2 + 15a + 5)(4a^6 + 30a^5 + 65a^4 - 200a^2 - 125a + 125)}{(a^4 + 5a^3 + 15a^2 + 25a + 25)^3}.$

Here it satisfies that $v_{\mathfrak{p}}(\gamma^2 - 1) = 2v_5(\widetilde{\mu}) + 1$. If $v_5(a) \leq -1$, then $v_5(\widetilde{\mu}) \geq 4$. When $v_5(a-2) \geq 1$, one has $v_5(\widetilde{\mu}) \geq 3$. For the case $v_5(a) = v_5(a-2) = 0$, we have $v_5(\widetilde{\mu}) = 2$. The condition $v_5(a) \geq 1$ implies that $v_5(\widetilde{\mu}) = 0$. Hence L/\mathbb{Q} is ramified at 5 if and only if $v_5(a) \geq 1$.

By the argument in the proof of Proposition 5.6 one sees

Corollary 5.7. For a rational integer $a \in \mathbb{Q}$, the prime number 5

 $\begin{cases} \text{ramifies} & \text{if } v_5(a) \ge 1, \\ \text{remains prime} & \text{if } v_5(a) = v_5(a-2) = 0, \\ \text{splits completely} & \text{otherwise}, \end{cases}$

in the extension $\text{Spl}_{\mathbb{Q}}f_5(a, X)/\mathbb{Q}$.
