STOPPED DECISION PROCESSES ON
COMPACT METRIC SPACES

By

Seiichi Iwamoto*

(Received February 5, 1970)

§ 1. Introduction.

A stopped decision process is specified by six objects: S, A, q, r, g and α. S, the
set of the possible states of some system, is a non-empty Borel subset of a Polish
space and A, the set of actions available to you, is a non-empty Borel subset of the
Polish space. At each time n, suppose that when the system is in s two alternatives
are possible (a) action a is chosen or (b) the next sampling is terminated (stopped).
The election (a) moves the system to a new state s' (which will be the state you
observe tomorrow) according to the distribution q(· | s, a) and consequently you receive
a reward r(s, a, s'), and election (b) terminates the process and you will receive the
terminal reward g(s). Since α (< 1) is a discount factor, unit reward on the n-th
day is worth only α^n-1.

A stopped policy is pair (π, τ). The policy π is a sequence π₁, π₂, ... where πₙ
tells you how to select an action on the n-th day as a function of the previous
history h = (s₁, a₁, ..., aₙ₋₁, sₙ) of the system, by associating with each h (Borel
measurably) a probability distribution πₙ(· | h) on the Borel field of A. τ is an
essentially finite, non-anticipative integer valued random variable. Then such a τ
defines a stopping rule: If τ = n, then choose (b) and the process is terminated at
time n; if τ > n choose (a) at time n and the system goes to (n+1)-st stage.

The stopped policy (π, τ) associates with each initial state s₁ a corresponding
n-th day return

\[ \sum_{k=1}^{n-1} α^{k-1} r(s_k, a_k, s_{k+1}) + α^{n-1} g(s_n) \]
at τ = n, where for each k, sₖ is the state of the system, and aₖ the action at time k.

Note that only when you take the stopping rule τ = n, you can receive an income
which is the sum of the discounted reward by choosing (a) up to date and the dis-
counted one gained by stopping at τ = n.

The stopped decision problem is to maximize your total expected reward over
the future

A Baire function f from S into A defines a policy: when in state s at time n,
choose an action f(s) independently of when and how you have arrived at state s,
where τ is the paired stopping time. Such a policy will be called stationary policy,

* Department of Mathematics, Kyushu University, Fukuoka.
which is denoted by $f^{(s)}$. A stationary stopped-policy is one whose policy is stationary and whose stopping time is Markov (Section 3).

Recently the stopped decision problem has been studied extensively by N. Furukawa and S. Iwamoto ([2]), and the existence of stationary stopped-policies, which are optimal in some senses, was shown under some assumptions.

In this paper, we will make three additional assumptions about $A$, $q$, $r$ and $g$. In Section 4, the following assumptions will remain operative; (1) $A$ is a compact metric space, (2) $r(s, a, s') = r^*(s, a) + r^{**}(s')$, where $r^*$, $r^{**}$ and $g$ are bounded upper semi-continuous and (3) if $s_n \to s$, $a_n \to a$, then $q(\cdot | s_n, a_n)$ converges weakly to $q(\cdot | s, a)$. Our result is the following: under these assumptions, always exists an $\varepsilon$-optimal stationary stopped-policy for any $\varepsilon > 0$.

Our method of proof is based on two facts; (A) The optimality equation has at most one bounded solution ([2]), and (B) Selection Theorem, due to Dubins and Savage ([3]), which was proved by A. Maitra in detail.

In Section 2 we give the notations and definitions to be used throughout this paper, and in Section 3 we shall define the stopped decision process. Section 4 is devoted to the existence theorem of $\varepsilon$-optimal stationary stopped policy, preparing the fundamental lemmas.

§ 2. Notations and probabilistic definitions.

This section is devoted to an exposition of the basic notations and probabilistic definitions needed for the following sections. We follow [2] as closely as possible.

By a Borel set we mean a Borel subset of some Polish (i.e. complete separable metric) space. By a probability measure on a non-empty Borel set $X$ we mean a probability measure defined on the Borel field of $X$, and the class of all probability measures on $X$ is denoted by $P(X)$. For any non-empty Borel sets $X$, $Y$, a conditional probability measure on $Y$ given $X$ is denoted by $P(Y|X)$. The class of all bounded Baire functions on $X$ is denoted by $C_b(X)$. $C_b(X)$ is the class of all bounded upper semi-continuous functions on $X$. It is clear that $C_b(X) \subseteq M(X)$. If $u, v \in M(X)$, $u \geq v$ means $u(x) \geq v(x)$ for all $x \in X$. For any $p \in P(X)$ and any $u \in M(X)$, $pu$ denotes the integral of $u$ with respect to $p$. The product space of $X$ and $Y$ will be denoted by $XY$. For any $u \in M(XY)$ and any $q \in Q(Y|X)$, $q u$ denotes the element of $M(X)$ whose value at $x_0 \in X$ is given by $q u(x_0) = \int_Y u(x_0, y) dq(y|x_0)$.

A $p \in P(X)$ is degenerate if $p(x_0) = 1$ for some $x_0 \in X$, and a $q \in Q(Y|X)$ is degenerate if $q(\cdot | x)$ is degenerate for each $x$. The degenerate $q$ are exactly those for which there is a Baire function $f$ mapping $X$ into $Y$ such that

$$q(\{ f(x) \} | x) = 1 \quad \text{for all } x \in X.$$ 

Any such function $f$ will also denote its associated degenerate $q$, so that, for any $u \in M(XY)$,

$$fu(x) = u(x, f(x)) \quad \text{for all } x \in X.$$
§ 3. Stopped decision processes.

In general the optimization problem in our stopped decision processes is defined by six elements $S$, $A$, $g$, $r$, $g$ and $\alpha$. The state space $S$ and the action space $A$ are non-empty Borel sets, and the law of motion $q$ is a sequence of transition probabilities; $q = \{q_0, q_1, \ldots\}$, where each $q_n \in Q(S|H_nA)$ and $H_n = SA \ldots S(2n-1 \text{ factors})$ is the set of possible histories of the system when the $n$-th alternative must be chosen. The immediate reward function $r$ is a Baire function on $SAS$, the terminal reward function $g$ is a Baire function on $S$ and $\alpha$ is a discount factor, $0 \leq \alpha < 1$.

But we treat the case only where

$$r \in M(SAS) \quad \text{and} \quad g \in M(S).$$

A policy $\pi$ is a finite sequence $\{\pi_1, \pi_2, \ldots, \pi_N\}$ or a denumerable sequence $\{\pi_1, \pi_2, \ldots\}$, where each $\pi_n \in Q(A|H_n)$. The policy $\pi$ is Markov if each $\pi_n$ is a degenerate element of $Q(A|S)$, i.e., $\pi = \{f_1, f_2, \ldots\}$, where each $f_n$ is a Baire function from $S$ into $A$, and stationary if it is Markov and there exists a Baire function $f$ from $S$ into $A$ such that $\pi_n = f$ for all $n$.

Any policy $\pi$, together with $q$, defines a conditional probability on the countable product set $ASAS\ldots$ given that the initial state $s_1$, i.e., it defines

$$e_\pi = \pi_1q_1\pi_2q_2\ldots \in Q(ASAS\ldots|S).$$

Let $\mathcal{G}$ and $\mathcal{A}$ be the Borel fields of $S$ and $A$ respectively. Let the sample space $\Omega = SASAS\ldots$. The sample point $\omega$ is expressed as $\omega = (s_1, a_1, s_2, a_2, \ldots)$, where each $s_n \subseteq S$ and each $a_n \subseteq A$. $\mathfrak{g}_n$ denotes the family of all unions of sets in $\Omega$ of the form

$$\{\omega | s_1 \subseteq E_1, a_1 \subseteq F_1, s_2 \subseteq E_2, a_2 \subseteq F_2, \ldots, s_n \subseteq E_n\}$$

where $E_i \in \mathcal{G}$ and $F_i \in \mathcal{A}$ for $i = 1, 2, \ldots, n$. Let $\pi$ be any policy. Then a stopping time associated with $\pi$ is a random variable $t = t(\omega)$ with positive integer values such that

$$e_\pi[\{t(\omega) < \infty\}|s_1] = 1 \quad \text{for all} \quad s_1 \subseteq S$$

and

$$\{t(\omega) = n\} \in \mathfrak{g}_n \quad \text{for each} \quad n$$

where by $\{\ldots\}$ we mean the set of all $\omega$ for which the indicated relation holds, and $\{\ldots\}_{s_1}$ means the $s_1$-section of the $\omega$-set. Let $C(\pi)$, for each $\pi$, be the class of all stopping times associated with $\pi$. For any policy $\pi$ and $t \in C(\pi)$, a pair $(\pi, t)$ is called the stopped-policy (abbreviated as $s$-policy). $C^N(\pi)$ denotes the class of all stopping times $t \in C(\pi)$ for which

$$e_\pi[\{t(\omega) \leq N\}_{s_1}] = 1 \quad \text{for all} \quad s_1 \subseteq S.$$

An $s$-policy $(\pi, t)$ is called the truncated-policy (abbreviated as $t$-policy) if there exists an integer $N$ such that

$$t \in C^N(\pi).$$

Let $\mathfrak{S}_n$ denote the family of all unions of sets in $\Omega$ of the form

$$\{\omega | s_1 \subseteq E_1, s_2 \subseteq E_2, \ldots, s_n \subseteq E_n\}$$
where \( E_n \in \mathcal{E} \) and \( \mathcal{E}_n \) the family of all \( \omega \)-sets of the form
\[
\{ \omega \mid s_n \in E_n \}
\]
where \( E_n \in \mathcal{E} \). A \( t \in \mathcal{C}(\pi) \) is Markov if for each \( n \)
\[
\{ t(\omega) = n \} \in \mathcal{F}_n
\]
and \( \{ t(\omega) = n \} \) can be written in the form
\[
\{ t(\omega) = n \} = \{ t(\omega) > n-1 \} \cap J_n \quad \text{for each } n
\]
where \( J_n \in \mathcal{G}_n \). An \( s \)-policy \( (\pi, t) \) is Markov if both \( \pi \) and \( t \) are Markov. A Markov \( s \)-policy is stationary, if \( \pi \) is so. A Markov \( t \in \mathcal{C}(\pi) \) is stationary, if \( J_n \) does not depend on \( n \).

Let
\[
\begin{align*}
x_n &= \sum_{k=1}^{n-1} \alpha^{k-1} r(s_k, a_k, s_{k+1}) + \alpha^{n-1} g(s_n) \\
&= \sum_{k=1}^{n-1} \alpha^{k-1} r_k + \alpha^{n-1} g_n \quad \text{for each } n,
\end{align*}
\]
where \( r_k = r(s_k, a_k, s_{k+1}) \) and \( g_n = g(s_n) \).

\( E^\pi \) denotes the expectation with respect to \( e_\pi \). The expected total reward from an \( s \)-policy \( (\pi, t) \), as a function of the initial state \( s_i \), is then
\[
E^\pi(x_\pi)(s_i) = \int_{\mathcal{A} \times \mathcal{S}} x_t \, d\pi(e, s_i)
\]
\[
= \sum_{n=1}^{\infty} \int_{\{ t = n \}} x_n \, d(\pi_1, \pi_2, \pi_3, \ldots, \pi_{n-1}, q_{n-1})(\cdot \mid s_i)
\]
\[
= \sum_{n=1}^{\infty} \int_{\{ t = n \}} \left[ \sum_{k=1}^{n-1} \alpha^{k-1} r_k + \alpha^{n-1} g_n \right] \, d(\pi_1, \pi_2, \pi_3, \ldots, \pi_{n-1}, q_{n-1})(\cdot \mid s_i)
\]
\[
= \int_{\mathcal{A} \times \mathcal{S}} \left[ \sum_{k=1}^{n-1} \alpha^{k-1} r_k + \alpha^{n-1} g_n \right] \, d\pi(e, s_i).
\]

Let \( \Pi \) denote the class of all policies and \( A \) the class of all stopped policies, i.e.
\[
A = \{ (\pi, t) \mid \pi \in \Pi, t \in \mathcal{C}(\pi) \}.
\]
An \( s \)-policy \( (\pi^*, t^*) \) is called \( \varepsilon \)-optimal if
\[
E^\pi(x_\pi) \geq E^\pi(x_\pi) - \varepsilon \quad \text{for every } (\pi, t) \in A
\]
and is called optimal if
\[
E^\pi(x_\pi) \geq E^\pi(x_\pi) \quad \text{for every } (\pi, t) \in A.
\]

§ 4. \( s \)-optimal stationary stopped-policies.

In this section we shall assume that \( A \) is a compact metric space, \( r \) a bounded upper semi-continuous function on \( \mathcal{A} \times \mathcal{S} \), \( q \) a bounded upper semi-continuous function on \( \mathcal{S} \), and \( q_1 = q_2 = \ldots = q \in Q(\mathcal{S} \mid \mathcal{A}) \) is continuous, that is, \( (s_n, a_n) \rightarrow (s, a) \) implies that \( q(\cdot \mid s_n, a_n) \) converges weakly to \( q(\cdot \mid s, a) \).
We consider the case only where the discount factor $\alpha < 1$, and the motion-law of the system is homogeneous Markov. We shall use the notations and lemmas closely those of [2].

With any degenerate $f \in Q(A|S)$ we associate the operators $T_f$ and $A_f$, mapping $M(S)$ into $M(S)$ defined by

$$T_f u(s) = \int [r(s, f(s), \cdot) + \alpha u(\cdot)] dq(\cdot | s, f(s)) \quad (4.1)$$

$$A_f u(s) = \max \{ g(s), T_f u(s) \} \quad (4.2)$$

respectively. $T_f u(s)$ may be interpreted as the expected return if you are in state $s$, take an action $f(s)$, and receive a final return $u(s')$ at the resulting state $s'$. $A_f u(s)$ is the optimal return, when the system allows you to select two possible alternatives in the state $s$ (a) taking an action $f(s)$ or (b) terminating the process.

The following properties of the operators $T_f$, $A_f$, formulated as a lemma, are immediate from the definition.

**Lemma 4.1.** (a) $T_f$, $A_f$ are monotone operators.
(b) For any $u \in M(S)$, constant $c$, $T_f (u + c) = T_f u + c$.
(c) For any $u \in M(S)$, constant $c > 0$, $A_f (u + c) \leq A_f u + c$.

**Proof.** The proofs are stated in Lemma 7.1 of [2].

Here are some basic properties which will take an important role in proving our desired results.

**Lemma 4.2.** (a) With any Baire function $f : S \to A$, the operator $A_f$ is a contraction mapping on $M(S)$ with contraction coefficient $\alpha$.
(b) For any $u, v \in M(S)$ and any Markov policy $\pi = (f_1, f_2, \ldots)$, it holds that

$$\lim_{n \to \infty} \| A_{f_1} A_{f_2} \cdots A_{f_n} u - A_{f_1} A_{f_2} \cdots A_{f_n} v \| = 0.$$  

**Proof.** (a), (b) are stated in Lemma 7.2 of [2].

We say that a $u \in M(S)$ satisfies the optimality equation, if it holds that

$$u = \sup_{A} A_{\alpha} u,$$

where $A_{\alpha}$ is the operator $A_{\alpha}$ with $\beta \equiv \alpha$. The principal general result on the optimality equation is contained in the following lemma.

**Lemma 4.3.** The optimality equation has at most one bounded solution.

**Proof.** This lemma is stated as Lemma 7.15 in [2].

But under the assumptions stated at the beginning of this section it will be shown that the optimality equation has a unique bounded solution in $C_0(S)$.

On the other hand we introduce a process $\{ \beta_n^\pi, n = 1, 2, \ldots, N \}$ for any fixed integer $N \geq 1$, which is closely related to the operator $A_f$. For any policy $\pi$ we define for each $N \geq 1$ a finite sequence of random variables $\{ \beta_n^\pi \} ; 1 \leq n \leq N$, by backward induction:

$$\beta_n^\pi(\pi) = \max \{ x_n, \pi_n q_n(\beta_{n+1}^\pi(\pi)) \}, \quad n = 1, 2, \ldots, N - 1,$$

$$\beta_N^\pi(\pi) = x_N.$$  

(4.3)

We now define the stopping time $\tau_N$. 

\[ \tau_N(\pi) = \text{the first integer } n \text{ such that } \beta_N(\pi) = x_n. \quad (4.4) \]

Then it is obvious that
\[ \tau_N(\pi) \in C_N(\pi). \]

Let
\[ \alpha_{n-1} \beta_N(\pi) = \beta_n(\pi) = \sum_{k=1}^{\infty} a_{k-1} r_k, \]

(4.3) then turns out to become
\[
\begin{cases}
\nu_N(\pi) = \max \{ g_n, \pi_n q_n \{ \alpha \nu_N(\pi) + r_n \} \}, & n = 1, 2, \ldots, N-1, \\
\nu_N(\pi) = g_N.
\end{cases}
\]

We shall need the following lemma, in particular, for the stationary policy \( \pi = f^{\pi}. \)

**Lemma 4.4.** (a) \( E(\pi) = E(\beta_N(\pi)) = v(\pi) = v(\pi). \)

(b) Let \( z_N(\pi) \) be defined by (4.4), then it follows that \( z_N(\pi) = \text{the first integer } n \text{ such that } v_n(\pi) = g_n. \)

(c) For any Markov \( \pi = \{ f_1, f_2, \ldots \} \)
\[ A_f A_f^2 \cdots A_f^N g = v_N(\pi) \quad \text{for each } N \geq 1. \]

**Proof.** Lemma 4.5 and 6.2 in [2] show these results.

We have the following lemma, the proof of which is due to [1].

**Lemma 4.5.** Let \( u \) be a bounded upper semi-continuous on \( S \). Define \( u^* : S \rightarrow \mathbb{R} \) by
\[ u^*(s) = \max_{a \in A} u(s, a). \]

Then \( u^* \) is bounded upper semi-continuous.

**Lemma 4.6.** Let \( w : S \rightarrow \mathbb{R} \) be a bounded upper semi-continuous. The \( h : SA \rightarrow \mathbb{R} \) defined by
\[ h(s, a) = \int w(\cdot) dq(\cdot | s, a) \]
is bounded upper semi-continuous.

**Proof.** If \( w \) is continuous, then clearly \( h \) is continuous. Now if \( w \) is bounded and upper semi-continuous, there exists a sequence of bounded continuous functions \( \{ w_n, n = 1, 2, \ldots \} \) such that
\[ w_n \downarrow w \quad \text{on } S. \]

Let \( h_n(s, a) : SA \rightarrow \mathbb{R} \) be defined by
\[ h_n(s, a) = \int w_n(\cdot) dq(\cdot | s, a). \]

Each \( h_n \) is continuous and, moreover, by the dominated convergence theorem,
\[ h_n \downarrow h \quad \text{on } SA. \quad (4.5) \]

If \( (s_n, a_n) \rightarrow (s, a) \), then for any \( \varepsilon > 0 \) there exist integers \( N_1, N_2 \) such that
\[ n \geq N_1 \text{ implies } h_n(s, a) \leq h(s, a) + \frac{\varepsilon}{3} \quad (4.6) \]
and
\[ m \geq N_2 \text{ implies } |h_n(s, a) - h_m(s, a)| \leq \frac{\varepsilon}{3} \quad \text{for } n = 1, 2, \ldots. \]
Therefore
\[ m \geq N_2 \text{ implies } h_n(s_m, a_m) \leq h_n(s, a) - \frac{\varepsilon}{3} \text{ for } n = 1, 2, \ldots. \] (4.7)

By (4.5),
\[ h(s_m, a_m) \leq h_n(s_m, a_m) + \frac{\varepsilon}{3} \text{ for } n = 1, 2, \ldots. \] (4.8)

Combining these results expressed in (4.6), (4.7) and (4.8) yields the desired relation

\[ n \geq N_1 \text{ and } m \geq N_2 \text{ imply } h(s_m, a_m) \leq h(s, a) + \varepsilon. \]

Since \( \varepsilon \) is arbitrary we obtain
\[ \limsup_{m \to \infty} h(s_m, a_m) \leq h(s, a). \]

Clearly \( h \) is bounded. This completes the proof.

The following theorem due to Dubins and Savage ([3]), was proved in detail by A. Maitra ([1]).

Selection Theorem (A. Maitra [1]): Let \( u \) be a bounded upper semi-continuous function on \( S \times A \). Then there exists a Baire function \( f \) from \( S \) into \( A \) such that
\[ u(s, f(s)) = \max_{a \in A} u(s, a) \text{ for all } s \in S. \]

For \( u, v \in C(S) \) we define \( d_1 \) by
\[ d_1(u, v) = \|u - v\| = \sup_{s \in S} |u(s) - v(s)|, \]
then the following lemma is established by A. Maitra ([1]).

Lemma 4.7. \( (C(S), d_1) \) is a complete metric space.

Proof. It suffices to show that \( C(S) \) is closed under the uniform convergence. The detailed proof will be omitted here.

Throughout the remainder of this section we will assume that
\[ r = r^* + r^{**} \]
where \( r^* \in C(SA) \), \( r^{**} \in C(S) \) and \( r(s, a, s') = r^*(s, a) + r^{**}(s') \). This decomposition of \( r \) into \( r^* \) and \( r^{**} \) means that the reward \( r^{**}(s') \) related to the new state \( s' \) is free from the current state \( s \) and current action \( a \). Of course \( r^* \) and \( r^{**} \) are not necessarily constant sign. Therefore this restriction on \( r \) is rather slight.

For any \( u \in C(S) \), let \( A_u : S \to R \) be the function defined by
\[ A_u(s) = \max_{a \in A} A_u(a, s). \] (4.9)

Note that the operator \( T_a = T_r \), where \( f = a \), which is the contraction mapping on \( M(S) \), maps \( C(S) \) into \( C(S) \), since for \( u \in C(S) \)
\[ T_a u(s) = \int_S [r(s, a, \cdot) + au(\cdot)] dq(\cdot | s, a) \]
\[ = \int_S [r^*(s, a) + r^{**}(\cdot) + au(\cdot)] dq(\cdot | s, a) \]
\[ = r^*(s, a) + \int_S [r^{**}(\cdot) + au(\cdot)] dq(\cdot | s, a) \]
implies $T_a u \equiv C(S)$ for each $a \in A$ because of Lemma 4.6. It is also a contraction mapping on $C(S)$ with contraction coefficient $\alpha$ for all $a \in A$. Since for $u, v \in C(S)$ max $\{u, v\} \in C(S)$, (4.2) implies that the operator $A_a$ is a contraction mapping on $C(S)$ with contraction coefficient $\alpha$ for all $a \in A$.

For any $u \in C(S)$, from (4.9)

$$Au(s) = \max_a \max \left[ g(s), \int_S [r(s, a, \cdot) + \alpha u(\cdot)] dq(\cdot | s, a) \right]$$

$$= \max_a \max \left[ g(s), \int_S [r^*(s, a) - r^{**}(\cdot) + \alpha u(\cdot)] dq(\cdot | s, a) \right]. \quad (4.9)'$$

In this expression, $r^{**}(\cdot) - \alpha u(\cdot)$ is upper semi-continuous on $S$ and by virtue of Lemma 4.6 integral within square bracket on the right-hand side of (4.9)' is upper semi-continuous in $(s, a)$. Consequently

$$\max \left[ g(s), \int_S [r(s, a, \cdot) + \alpha u(\cdot)] dq(\cdot | s, a) \right] \quad (4.10)$$

is also upper semi-continuous in $(s, a)$, and maximum is attained for all $s \in S$ because the action space $A$ is compact. Since (4.10) is obviously bounded, Lemma 4.5 implies that $Au$ is upper semi-continuous. Thus the operator $A$ maps $C(S)$ into $C(S)$.

**Lemma 4.8.** The operator $A$ defined by (4.9) is a contraction mapping on $C(S)$ with contraction coefficient $\alpha$, and consequently, has a unique fixed point.

**Proof.** Let $u_1, u_2 \in C(S)$. Clearly $u_1 \leq u_2 + \|u_1 - u_2\|$. Lemma 4.1 yields

$$A_a u_1 \leq A_a (u_2 + \|u_1 - u_2\|) \leq A_a u_2 + \alpha \|u_1 - u_2\| \quad \text{for all } a \in A.$$  

Then

$$\sup_{a \in A} A_a u_1 \leq \sup_{a \in A} (A_a u_2 + \alpha \|u_1 - u_2\|) = \sup_{a \in A} A_a u_2 + \alpha \|u_1 - u_2\|.$$  

In this case `sup` can be replaced by `max` because of the Lemma 4.5. Therefore

$$A u_1 - A u_2 \leq \alpha \|u_1 - u_2\|.$$  

Interchanging $u_1$ and $u_2$, we get

$$A u_2 - A u_1 \leq \alpha \|u_1 - u_2\|.$$  

Hence, $\|A u_1 - A u_2\| \leq \alpha \|u_1 - u_2\|$, which proves that operator $A$ is a contraction mapping, as $\alpha < 1$. Since $C(S)$ is a complete metric space (Lemma 4.7), it follows from the Banach Fixed Point theorem that the operator $A$ has a unique fixed point in $C(S)$. This completes the proof.

We set the following assumptions.

(H1) $r = r' - r''$, where $r'$ and $r''$ are the real-valued Baire functions on $S$ and $r^\sigma \geq 0$.

(H2) $E^\sigma(x) < \infty$ for all $(\pi, i) \in A$, where $x^\pi = \sum_{k=1}^{n-1} \alpha^{k-1} r'(s_k, a_k, s_{k+1}) + \alpha^{n-1} g(s_n)$.

(H3) $(x^{\pi^0}_n, n \geq 1)$ is uniformly integrable w.r.t. $\pi$ for each $\pi \in \Pi$, where $a^- = \max (0, -a)$.

The following lemma is given as Lemma 7.12 in [2].

**Lemma 4.9.** Let (H1), (H2) and (H3) be satisfied. Any $u \in M(S)$ for which $A_a u \leq u$
for all \( a \in A \) satisfies that \( E^\pi(x_i) \leq u \) for all \((\pi, t)\) \( \in A \).

Finally we have the desired result on the basis of above lemmas.

**Theorem.** Assume (H1), (H2) and (H3). Then for any \( \varepsilon > 0 \) there exists an \( \varepsilon \)-optimal stationary \( s \)-policy which is \( t \)-policy.

**Proof.** By Lemma (4.8) the operator \( A \) has a unique fixed point \( u^* \) in \( C_1(S) \), so that

\[
11^* = Au^* = \max_{a \in A} A_au^*, \quad \text{where } u^* \in C_1(S).
\]

For this \( u^* \), function \( u:SA \rightarrow R \) defined by

\[
u(s, a) = \max \left[ g(s), \int_S [r(s, a, \cdot) + \alpha u^*(\cdot)] dq(s, a) \right]
\]
is bounded upper semi-continuous on \( SA \). From the Selection Theorem there exists a Baire function \( f \) from \( S \) into \( A \) such that

\[
u(s, f(s)) = \max_{a \in A} u(s, a) \quad \text{for all } s \in S.
\]

Consequently this function defines the operator \( A_f \) on \( M(S) \) such that

\[
u^* = Au^* = \max_{a \in A} A_au^* = A_fu^*.
\]

On the other hand from the Lemma 4.2 the operator \( A_f \) is a contraction mapping on \( M(S) \). Then by virtue of Banach Fixed Point theorem, it has a unique fixed point \( w^* \)

\[
A_fw^* = w^*, \quad \text{where } w^* \in M(S).
\]

The uniqueness of the fixed point of \( A_f \) together with the fact \( C_1(S) \subseteq M(S) \) yields

\[
u^* = w^*.
\]

Hence \( A_fv^* = v^* \), so that \( (A_f)^nv^* = v^* \) for all \( n \geq 1 \). From Lemma 4.2, for any \( \varepsilon > 0 \) there exists an integer \( N \) such that \( n \geq N \) implies

\[
(A_f)^{n-1}g \geq (A_f)^{n-1}u^* - \varepsilon = u^* - \varepsilon.
\]

Since \( u^* \) satisfies the optimality equation, \( u^* \geq A_au^* \) for all \( a \in A \).

Then by Lemma 4.9

\[
u^* \geq E^\pi(x_i) \quad \text{for all } (\pi, t) \in A.
\]

Combining the results expressed in (4.12) and (4.13) yields the relation

\[
(A_f)^{n-1}g \geq E^\pi(x_i) - \varepsilon \quad \text{for any } (\pi, t) \in A, \quad \text{where } n \geq N.
\]

Lemma 4.4 allows us to write

\[
E^\pi(x_\tau_{n,f}) = (A_f)^{n-1}g
\]

where \( f^{(\cdot)} = (f, f, \ldots) \) and

\[
\tau_\pi(f) = \text{the first integer } k \text{ such that } v_k^*(f^{(\cdot)}) = g_k.
\]

Finally, using (4.14) and (4.15) we obtain the final relation

\[
E^{(\cdot)}(x_{\tau_n(f)}) \geq E^\pi(x_i) - \varepsilon \quad \text{for all } (\pi, t) \in A \quad \text{and } n \geq N.
\]
It is obvious that $s$-policy $(f^{(n)}, \tau_n(f))$ is truncated, i.e.

$$(f^{(n)}, \tau_n(f)) \in C^s(f^{(\infty)})$$

and that it is $s$-optimal stationary $s$-policy for $n \geq N$. This completes the proof.

Moreover if we put the following assumptions in addition to (H1) and (H3) we can find an optimal $s$-policy which has a stationary stopping time.

(H4) \( \lim_{n \to \infty} x_n^\pi = +\infty \) \( w.e. \), for all \( \pi \in \Pi \), where \( x_n^\pi = \sum_{k=1}^{\infty} \alpha_k^{-1} r^\pi(s_k, a_k, s_{k+1}) \).

(H5) (i) \( (x_n^\pi, n \geq 1) \) is uniformly integrable \( w.r.t. e_n \), and (ii) \( \sup_{n} E^{f^{(n)}}(x_n^\pi f) < \infty \) for every stationary \( f^{(\infty)} \).

**Corollary.** Assume (H1), (H2), (H4) and (H5). Then there exists an optimal stationary $s$-policy having a stationary stopping time.

**Proof.**

$$\lim_{n \to \infty} (A_n)^{n} g = v_t(f^{(\infty)}) = u^*, \quad v_n(f^{(\infty)}) = \lim_{N \to \infty} v_n^N(f^{(\infty)})$$

and $\tau$ be the first $n$ such that $v_n(f^{(\infty)}) = g_n$.

The arguments in [2], Corollary 7.2, Theorem 8.2, show us the facts

$$\tau \in C(f^{(\infty)})$$

and

$$\sup_{(t \in C(f^{(\infty)}))} E^{f^{(n)}}(x_t) = \lim_{N \to \infty} E^{f^{(n)}}(x_{\tau,N,N} f),$$

which completes the proof.

In conclusion we remark that in paper [1], even if $r(s, a)$ is replaced by $r(s, a, s') = r^*(s, a) - r^{**}(s')$, where $r^*(s, a) \in C_1(S,A)$, $r^{**}(s') \in C_1(S)$, the Maitra’s result remains true: there exists a stationary plan.

Acknowledgement. I would like to thank Dr. N. Furukawa, under whose guidance this paper was prepared.
