ON THE PATTERN CLASSIFICATION BY LEARNING

By

Kensuke Tanaka*

(Received December 25, 1970)

§ 1. Introduction and Summary

This paper is a continuation of our papers ([10], [11], [12]) and is concerned with the pattern classification related to "learning with a teacher" and "learning without a teacher". In the problem related to "learning with a teacher", we tried to find an algorithm by which, for two given categories, we can construct, from a training sequence, a sequence of linear systems of orthonormal functions to get an approximation to a sequence of the Bayes decision functions which are optimum in the sense of minimizing the probability of misclassification at each instant.

Now, we recall the algorithm of learning developed in [13]. In [13], the approximation to the Bayes decision functions for each fixed point of domain is nonparametric and the existence of a training sequence from the independent random variables is assumed. However, it does not seem general enough that the patterns are observed from the independent random variables in the statistical pattern recognition. On this reason, we replace the above assumption by weaker one that the patterns are observed from the dependent random variables with certain conditions. In the above situation, we shall try to extend the algorithm of learning developed in [13].

Next, in the problem related to "learning without a teacher", we pay attention to the algorithm of learning developed in [9]. In [9], the probability density function of the patterns is the following form:

$$p(x) = \sum_{i=1}^{s} q_i f_i(x),$$

where $q_i$ is a priori probability of the category $\theta_i$ and $f_i(x)$ is the probability density function of an observed pattern which belongs to the category $\theta_i$.

When $f_i(x)$ is known to the observer for all $i$, the algorithm is given for estimating a priori probabilities $q_i$, $i=1, 2, \cdots, s$, on the basis of the unclassified observed patterns. Here, we make the above situation weaker in the following two points: (i) the categories at each instant are from the dependent random variables with certain conditions, (ii) the probability density function is time-variant. In this situation, we shall try to extend the algorithm developed in [9].

Our algorithms in both learning are an application of the method introduced by T. Kitagawa [7] in the successive process of statistical control. This method, which

* Department of Mathematics Faculty of Science, Niigata University, Niigata.
may be called modified stochastic approximation, was investigated by V. Dušek [4]
in detail.

This paper consists of six sections. In Section 2, we shall state several lemmas
necessary for the proofs of main results of this paper. In Section 3, we shall give
the formulation of the problem in this paper. In Section 4, we shall investigate
"learning with a teacher" in the case when there are two categories. In Section 5,
we shall be concerned with "learning without a teacher" in the case when there
are many categories.

§ 2. Preliminaries

In this section, two lemmas are stated without proof in order to prove main
results of this paper. Let us consider an m-dimensional stochastic process \{y^n\}_{n=1}^\infty
and three sequences of non-negative real-valued measurable functions \{U_n\}_{n=1}^\infty,
\{V_n\}_{n=1}^\infty and \{\zeta_n\}_{n=1}^\infty, where each \(U_n, V_n\) and \(\zeta_n\) are defined on \(\mathbb{R}^{nm}\). Then accordingly
\(\{U_n(y^1, \ldots, y^n)\}_{n=1}^\infty, \{V_n(y^1, \ldots, y^n)\}_{n=1}^\infty\) and \(\{\zeta_n(y^1, \ldots, y^n)\}_{n=1}^\infty\)
become again three stochastic processes, respectively. Let us write \(U_n = U_n(y^1, \ldots, y^n), V_n = V_n(y^1, \ldots, y^n)\)
and \(\zeta_n = \zeta_n(y^1, \ldots, y^n)\) for the sake of simplicity. We denote the expected values of
three stochastic variables \(U_n, V_n\) and \(\zeta_n\) by \(E[U_n], E[V_n]\) and \(E[\zeta_n]\). Furthermore,
we denote the conditional expectations of three stochastic variables \(U_{n+1}, V_{n+1}\) and
\(\zeta_{n+1}\) given the random variables \(y^1, y^2, \ldots, y^n\) by \(E[U_{n+1}|y^1, \ldots, y^n], E[V_{n+1}|y^1, \ldots, y^n]\)
and \(E[\zeta_{n+1}|y^1, \ldots, y^n]\).

In what follows, let \(\{\gamma_n\}_{n=1}^\infty\) and \(\{\mu_n\}_{n=1}^\infty\) be two sequences of real numbers. Now,
we introduce the fundamental conditions for three stochastic processes \(\{U_n\}_{n=1}^\infty,\n\{V_n\}_{n=1}^\infty\) and \(\{\zeta_n\}_{n=1}^\infty\):

(A1) \(E[U_1] \) and \(E[V_1] \) exist,

(A2) \(E[U_{n+1}|y^1, \ldots, y^n] \leq (1+\mu_n)U_n-\gamma_n V_n+\zeta_n \) hold for all \(n\),

(A3) \(\sum_{n=1}^\infty \gamma_n = \infty \) (\(\gamma_n \geq 0, n = 1, 2, \ldots\)),

(A4) \(\sum_{n=1}^\infty |\mu_n| < \infty\),

(A5) there exists a sequence of positive numbers \(\{M_n\}_{n=1}^\infty\) such that
\(P[\zeta_n \leq M_n] = 1\) for all \(n\),

and such that \(\sum_{n=1}^\infty M_n < \infty\).

The following Lemma 1 and Lemma 2 were essentially proved in [10].

Lemma 1. Let the hypotheses for three stochastic processes \(\{U_n\}_{n=1}^\infty, \{V_n\}_{n=1}^\infty\) and
\(\{\zeta_n\}_{n=1}^\infty\) be satisfied: (i) conditions (A1)-(A5) hold, (ii) \(\lim_{n \to \infty} \gamma_n = 0\), (iii) if there exists a
subsequence \(\{n_k\}_{k=1}^\infty\) of a sequence \(\{n\}_{n=1}^\infty\) such that \(P[\lim_{k \to \infty} V_{n_k} = 0] = 1\), then \(P[\lim_{k \to \infty} U_{n_k} = 0] = 1\). Then, it holds that
\(P[\lim_{n \to \infty} U_n = 0] = 1\) and \(\lim_{n \to \infty} E[U_n] = 0\) for all \(0 < \beta < 1\).

Lemma 2. Suppose that a sequence of non-negative real numbers \(\{a_n\}_{n=1}^\infty\) satisfies
the condition: there exist a positive integer \(n_0\), two sequences of non-negative real num-

\(\alpha=0\)
On the Pattern Classification by Learning

Let \( \{a_n\}^\infty_{n=1} \) and \( \{A_n\}^\infty_{n=1} \) such that

\[
\begin{align*}
(2.1) \quad a_{n+1} &\leq (1 - \gamma_{n+1})a_n + A_{n+1} \quad \text{for all } n \geq n_0, \\
(2.2) \quad \sum_{n=1}^\infty \gamma_n &= \infty, \\
(2.3) \quad \lim_{n \to \infty} \gamma_n = 0, \\
(2.4) \quad \sum_{n=1}^\infty A_n < \infty.
\end{align*}
\]

Then, it holds that \( \lim_{n \to \infty} a_n = 0. \)

Next, we mention without proof the lemma given by V. Dupač [4], a modification of the result of K.L. Chung.

**Lemma 3.** Let \( \{a_n\}^\infty_{n=1} \) be a sequence of non-negative real numbers. Suppose that there exist a positive integer \( n_0 \), two positive numbers \( A \) and \( B \) such that

\[
\begin{align*}
(2.5) \quad a_{n+1} &\leq (1 - \Lambda/n^n)a_n + B/n^n \quad \text{for all } n \geq n_0, \\
(2.6) \quad \text{real number and } 0 < s < 1.
\end{align*}
\]

Then, we have \( \lim \sup_{n \to \infty} n^{1-s}a_n \leq B/A. \)

§ 3. The formulation of the problem

In the pattern classification problem in this paper, each observed pattern \( x \) is a random sample taking value in \( \mathbb{R}^m \) from a group, to which they belong, and each group is called a category. Therefore, each observed pattern is drawn by a probability distribution law. Now, we consider the case when there exist \( s \) categories \( \theta_1, \theta_2, \ldots, \theta_s \) and we denote a set of these categories by \( \Theta \). Hence, each outcome in pattern classification is described by a pair \( (x, \theta) \). The element \( x \) is an observed pattern in a pattern space \( \mathbb{R}^m \) and \( \theta \) specifies the category of an observed pattern. But, generally, \( \theta \) is unknown to the observer. For a sequence of the observed patterns \( x_1, x_2, \ldots, x_n, \ldots \) we can consider a sequence:

\[
(3.1) \quad (x_1, \theta_1), (x_2, \theta_2), \ldots, (x_n, \theta_n), \ldots
\]

with \( x^n \in \mathbb{R}^m \) and \( \theta^n \in \Theta \), where \( \theta^n = \theta_i \) if \( x^n \) is from a specific category \( \theta_i \).

For such a sequence, the result of \( n \) history is expressed by two sets:

\[
\xi^n = (x_1, x_2, \ldots, x^n) \quad \text{and} \quad \alpha^n = (\theta_1, \theta_2, \ldots, \theta^n).
\]

In what follows, we shall assume that, for each \( n \), the transition probability distribution of an outcome at instant \( n+1 \) given a history at instant \( n \) has the density function w.r.t. Lebesgue measure and this is denoted by the following form:

\[
(3.2) \quad p(x^{n+1}, \theta^{n+1} | \alpha^n) = q^{(n+1)}(\theta^{n+1} | \alpha^n)f^{(n+1)}(x^{n+1}),
\]

where \( q^{(n+1)}(\theta^{n+1} | \alpha^n) \) is the conditional probability of a category \( \theta^{n+1} \) at instant \( n+1 \) given a history \( \alpha^n \) and \( f^{(n+1)}(x^{n+1}) \) is a conditional probability density function of the observed pattern \( x^{n+1} \) given a category \( \theta^{n+1} \) at instant \( n+1 \).
Now, we can consider "a posteriori" probability density function according to the Bayes formula: after an observed pattern $x^{n+1}$ at instant $n+1$ was known, we have the following "a posteriori" probability density function for $\alpha^n\theta^{n+1} = (\theta^1, \theta^2, \ldots, \theta^{n+1})$:

$$
\Pi_{x^{n+1}}(\alpha^n\theta^{n+1}) = \frac{\Pi(\alpha^n)q^{(n+1)}(\theta^{n+1} | \alpha^n)f_{\theta^{n+1}}(x^{n+1})}{\sum_{\alpha^n \in \Theta^n} \sum_{\theta^{n+1} \in \Theta} \Pi(\alpha^n)q^{(n+1)}(\theta^{n+1} | \alpha^n)f_{\theta^{n+1}}(x^{n+1})}
$$

where $\Theta^n = \Theta \times \Theta \times \cdots \times \Theta$ and $\Pi(\alpha^n)$ is a probability distribution on $\Theta^n$.

Then, if all transition probability density functions at each instant are known to the observer, the classification of an observed pattern at each instant will be determined by the largest of the quantities $\Pi_{x^{n+1}}(\alpha^n\theta_1)$, $\Pi_{x^{n+1}}(\alpha^n\theta_2)$, $\ldots$, $\Pi_{x^{n+1}}(\alpha^n\theta_s)$. From the statistical decision theory, it is well known that this decision rule is optimal, because of the minimum probability of misclassification, and that it is called the Bayes decision rule.

Hence, in the case when there are two categories, we have an optimum decision rule:

$x^{n+1}$ is classified in category $\theta_1$ if $D^*(x^{n+1} | \alpha^n) = 0$,

classified in category $\theta_2$ if $D^*(x^{n+1} | \alpha^n) < 0$,

where $D^*(x^{n+1} | \alpha^n) = \Pi_{x^{n+1}}(\alpha^n\theta_1) - \Pi_{x^{n+1}}(\alpha^n\theta_2)$.

This decision rule is equivalent to the following decision rule:

$x^{n+1}$ is classified in category $\theta_1$ if $D_0(x^{n+1} | \alpha^n) = 0$,

is classified in category $\theta_2$ if $D_0(x^{n+1} | \alpha^n) < 0$,

where $D_0(x^{n+1} | \alpha^n) = q^{(n+1)}(\theta_1 | \alpha^n)f^{(n+1)}_{\theta_1}(x^{n+1}) - q^{(n+1)}(\theta_2 | \alpha^n)f^{(n+1)}_{\theta_2}(x^{n+1})$.

§ 4. Learning with a teacher

In this section, we treat the case where the amount of a priori information on the transition probability density function at each instant is small but an observer is indicated by a teacher the category from which an observed pattern is extracted. By a training sequence, we shall imply a sequence $(x^1, \theta^1), (x^2, \theta^2), \ldots$, where $\theta^i$ is the category indicated by a teacher at instant $i$.

Now, when $\Theta = \{\theta_1, \theta_2\}$, we consider the problem of finding an algorithm of approximation to the Bayes decision function at each instant, on the basis of a training sequence. This decision which minimizes the probability of misclassification at each instant $n$ is the following form:

$$
D_0^n(x^n | \alpha^{n-1}) = q^{(n)}(\theta_1 | \alpha^{n-1})f_{\theta_1}(x^n) - q^{(n)}(\theta_2 | \alpha^{n-1})f_{\theta_2}(x^n).
$$

In what follows, each $f_{\theta_1}(x)$ is defined on $R^m$ and all integrals and supremums, unless otherwise indicated, are taken over $R^m$.

Here, let $K(\cdot)$ be a real-valued function on $R^m$ satisfying the following conditions:

(K1) \hspace{1cm} K(y) \geq 0 \quad \text{for all} \quad y \in R^m,

(K2) \hspace{1cm} \sup K(y) = K < \infty,
(K3) \[ \int K(y)dy = 1, \]

(K4) \[ \int \|y\|K(y)dy = K^* < \infty, \]

where the norm \( \|y\| = \sum_{i=1}^{n}(y_i)^2 \).

By using the above function \( K(\cdot) \), we shall construct the following algorithm with a sequence of positive real numbers \( \{h_n\}_{n=1}^{\infty} \) satisfying the condition:

(4.2) \[ 1 \geq h_1 \geq h_2 \geq \ldots \quad \text{and} \quad \lim_{n \to \infty} h_n = 0. \]

Firstly, using an outcome \((x_1, \theta_1)\) of an observed pattern \(x_1\) at instant 1 and a category \(\theta_1\) to which \(x_1\) belongs, indicated by a teacher, we make

(4.3) \[ D_1(x_1, x_1, \theta_1) = \rho^{(1)}(\theta_1)K_1(x_1, x_1) - (1 - \rho^{(1)}(\theta_1))K_1(x_1, x_1), \]

where

\[
K_1(x_1, x_1) = h_1^{-m}K[h_1^{-1}(x_1 - x_1)]
\]
and

\[
\rho^{(1)}(\theta_1) = \begin{cases} 1 & \text{if } \theta_1 = \theta_1 \\ 0 & \text{otherwise}. \end{cases}
\]

Secondly, using an outcome \((x_2, \theta_2)\) of an observed pattern \(x_2\) at instant 2 and a category \(\theta_2\), to which \(x_2\) belongs, indicated by a teacher, we make

(4.4) \[ D_2(x_1, x_2, \theta_2) = \rho^{(2)}(\theta_2)K_2(x_1, x_2) - (1 - \rho^{(2)}(\theta_2))K_2(x_1, x_2), \]

where

\[
K_2(x_1, x_2) = h_2^{-m}K[h_2^{-1}(x_1 - x_2)]
\]
and

\[
\rho^{(2)}(\theta_2) = \begin{cases} 1 & \text{if } \theta_2 = \theta, \\ 0 & \text{otherwise}. \end{cases}
\]

In general, using an outcome \((x_n, \theta_n)\) of an observed pattern \(x_n\) at instant \(n+1\) and a category \(\theta_n\), to which \(x_n\) belongs, indicated by a teacher, we make

(4.5) \[ D_n(x_n, \theta_n) = \rho^{(n+1)}(\theta_n)K_n(x_n, x_n) - (1 - \rho^{(n+1)}(\theta_n))K_n(x_n, x_n), \]

where

\[
K_n(x_n, x_n) = h_n^{-m}K[h_n^{-1}(x_n - x_n)]
\]
and

\[
\rho^{(n+1)}(\theta_n) = \begin{cases} 1 & \text{if } \theta_n = \theta_n \\ 0 & \text{otherwise}. \end{cases}
\]

The next lemma is necessary in order to prove the theorem in this section.

**Lemma 4.** Let \( f(\cdot) \) be a real-valued function on \( \mathbb{R}^m \) satisfying a uniform Lipschitz condition:
and $K(\cdot)$ satisfy (K1)~(K4). Then, it holds that

$$\|f_n(x) - f(x)\| \leq C K^* h_n,$$

where $f_n(x) = \int K_n(x, y) f(y) dy$.

**Proof.**

$$\|f_n(x) - f(x)\| = \left| \int K_n(x, y) (f(y) - f(x)) dy \right|$$

$$\leq \int K(z) |f(x - zh_n) - f(x)| dz$$

$$\leq C \int K(z) h_n z dz$$

$$= C K^* h_n.$$

Then, we can prove the following theorem concerning $D_{n+1}(x | \xi^{n+1}, \alpha^{n+1})$ and $D_0^{(n+1)}(x | \alpha^n)$.

**Theorem 4.1.** Let the following hypotheses be satisfied:

(i) $\int (f_i(x))^2 dx < \infty$ for all $i$,

(ii) $f_1(x)$ and $f_2(x)$ satisfy uniform Lipschitz condition,

(iii) $\sum n^{-1} h_n < \infty$ and $\sum n^{-2} h_n m < \infty$,

(iv) for each $i$, there exist a non-negative number $q_i (0 \leq q_i \leq 1, \sum q_i = 1)$ and a sequence of positive numbers $\{M_n\}_{n=1}^\infty$ such that

$$n(q^{(n)}(\theta_i | \alpha^{n-1}) - q_i)^2 \leq M_n$$

and such that $\sum n M_n < \infty$. Then, it holds that

$$P[\lim_{n \to \infty} I_n = 0] = 1$$

and

$$E[|I_\beta|] = 0$$

for all $0 < \beta < 1$.

**Proof.** By the construction of $D_{n+1}(x | \xi^{n+1}, \alpha^{n+1})$, we have

$$D_{n+1}(x | \xi^{n+1}, \alpha^{n+1}) - D_0^{(n+1)}(x | \alpha^n)$$

$$= \left(1 - \frac{1}{n+1}\right)D_n(x | \xi^n, \alpha^n) - \frac{1}{n+1} [\rho^{(n+1)}(\theta^{n+1}) K_{n+1}(x, x^{n+1})$$

$$- (1 - \rho^{(n+1)}(\theta^{n+1})) K_{n+1}(x, x^{n+1}) - D_0^{(n+1)}(x | \alpha^n)$$

$$+ \left(1 - \frac{1}{n+1}\right) [D_0^{(n)}(x | \alpha^{n-1}) - D_0^{(n+1)}(x | \alpha^n) ].$$

Hence, from (4.7), we can obtain
\[ I_{n+1} = \left(1 - \frac{1}{n+1}\right)^{2} I_{n} + \left(\frac{n}{n+1}\right)^{2} \Theta^{(n)} + \left(\frac{1}{n+1}\right)^{2} \int [Y_{n+1}(x, x^{n+1}) - D_{0}^{(n+1)}(x | \alpha^{n})]^{2} dx \]

\[ + 2 \left(\frac{n}{n+1}\right) \left(\frac{1}{n+1}\right) \int [D_{n}(x | \xi^{n}, \alpha^{n}) - D_{0}^{(n)}(x | \alpha^{n-1})][Y_{n+1}(x, x^{n+1}) - D_{0}^{(n+1)}(x | \alpha^{n})] dx \]

\[ + 2 \left(\frac{n}{n+1}\right) \left(\frac{1}{n+1}\right) \int [D_{0}^{(n)}(x | \alpha^{n-1}) - D_{0}^{(n+1)}(x | \alpha^{n})][Y_{n+1}(x, x^{n+1}) - D_{0}^{(n+1)}(x | \alpha^{n})] dx \]

\[ + 2 \left(\frac{n}{n+1}\right) \left(\frac{1}{n+1}\right) \int [D_{n}(x | \xi^{n}, \alpha^{n}) - D_{0}^{(n)}(x | \alpha^{n-1})][D_{0}^{(n)}(x | \alpha^{n-1}) - D_{0}^{(n+1)}(x | \alpha^{n})] dx , \]

where

\[ Y_{n+1}(x, x^{n+1}) = \rho^{(n+1)}(\theta^{n+1})K_{n+1}(x, x^{n+1}) - (1 - \rho^{(n+1)}(\theta^{n+1}))K_{n+1}(x, x^{n+1}) \]

and

\[ \Theta^{(n)} = \int [D_{0}^{(n)}(x | \alpha^{n-1}) - D_{0}^{(n+1)}(x | \alpha^{n})]^{2} dx . \]

Taking conditional expectation on both sides of (4.8), we have

\[ E[I_{n+1} | \xi^{n}, \alpha^{n}] = \left(1 - \frac{1}{n+1}\right)^{2} I_{n} + \left(\frac{n}{n+1}\right)^{2} \Theta^{(n)} \]

\[ + 2 \left(\frac{n}{n+1}\right) \left(\frac{1}{n+1}\right) E \left[ (D_{n}(x | \xi^{n}, \alpha^{n}) - D_{0}^{(n)}(x | \alpha^{n-1}))(Y_{n+1}(x, x^{n+1}) - D_{0}^{(n+1)}(x | \alpha^{n}) dx | \xi^{n}, \alpha^{n} \right] \]

\[ + 2 \left(\frac{n}{n+1}\right) \left(\frac{1}{n+1}\right) E \left[ (D_{0}^{(n)}(x | \alpha^{n-1}) - D_{0}^{(n+1)}(x | \alpha^{n}))(Y_{n+1}(x, x^{n+1}) - D_{0}^{(n+1)}(x | \alpha^{n}) dx | \xi^{n}, \alpha^{n} \right] \]

\[ + 2 \left(\frac{n}{n+1}\right) \left(\frac{1}{n+1}\right) E \left[ (D_{n}(x | \xi^{n}, \alpha^{n}) - D_{0}^{(n)}(x | \alpha^{n-1}))(D_{0}^{(n)}(x | \alpha^{n-1}) - D_{0}^{(n+1)}(x | \alpha^{n}) dx | \xi^{n}, \alpha^{n} \right] \]

Then, there exist two positive numbers \( M_{1}, M_{2} \) such that, from Lemma 4 and (K3),

\[ E[Y_{n+1}(x, x^{n+1}) - D_{0}^{(n+1)}(x | \alpha^{n}) | \xi^{n}, \alpha^{n}] | \]

\[ = \int K_{n+1}(x, y) [q^{(n+1)}(\theta_{1} | \alpha^{n})f_{\theta_{1}}(y) - q^{(n+1)}(\theta_{2} | \alpha^{n})f_{\theta_{2}}(y)] dy - D_{0}^{(n+1)}(x | \alpha^{n}) \]

\[ = \int K(x) [q^{(n+1)}(\theta_{1} | \alpha^{n})f_{\theta_{1}}(x - h_{n+1}z) - q^{(n+1)}(\theta_{1} | \alpha^{n})f_{\theta_{2}}(x - h_{n+1}z) \]

\[ - q^{(n+1)}(\theta_{1} | \alpha^{n})f_{\theta_{1}}(x) - q^{(n+1)}(\theta_{2} | \alpha^{n})f_{\theta_{2}}(x)] dz \]

\[ \leq M_{1}K^{*}h_{n+1} \]

and such that, from (K2) and (K3),

\[ E \left[ (Y_{n+1}(x, x^{n+1}) - D_{0}^{(n+1)}(x | \alpha^{n}))^{2} dx | \xi^{n}, \alpha^{n} \right] \]

\[ \leq 2E \left[ (Y_{n+1}(x, x^{n+1}))^{2} dx | \xi^{n}, \alpha^{n} \right] + 2 \left( D_{0}^{(n+1)}(x | \alpha^{n}) \right)^{2} dx \]
Furthermore, there exist two positive numbers \( M_3, M_4 \) such that, from (K3),
\[
\left| \int [D_0(x|\xi^n, \alpha^n) - D^{(n)}_0(x|\alpha^{n-1})] \, dx \right| \leq \frac{1}{n} \sum_{i=1}^{n} \int K_i(x, x^n) \, dx + \int [q^{(n+1)}(\theta_1|\alpha^n) f_{\theta_1}(x) + q^{(n+1)}(\theta_2|\alpha^n) f_{\theta_2}(x)] \, dx \\
\leq M_3
\]
and such that
\[
\left| \int [D_0^{(n)}(x|\alpha^{n-1}) - D^{(n+1)}_0(x|\alpha^n)] \, dx \right| \leq M_4.
\]

Noting that, for each instant \( n \),
\[
\left| 2 \int [D^{(n)}_0(x|\alpha^{n-1}) - D^{(n)}_0^{(n+1)}(x|\alpha^n)] \, dx \right| \leq \frac{1}{n+1} I_n + (n+1) \Theta^{(n)},
\]
from (4.9), (4.10), (4.11), (4.12), (4.13) and (4.14)
\[
E[I_{n+1} | \xi^n, \alpha^n] \leq \left[ 1 + \left( \frac{1}{n+1} \right)^2 I_n + \left( \frac{1}{n+1} \right)^2 (2K_{n+1}^m + 4M_2) + 2 \left( \frac{1}{n+1} \right) M_1 M_2 K h_{n+1} + 2 \left( \frac{1}{n+1} \right) M_1 M_2 K h_{n+1} + \left[ \left( \frac{1}{n+1} \right) I_n + (n+1) \Theta^{(n)} \right] \right]^{(n+1) \Theta^{(n)}}.
\]
Since there exists a positive number \( M_6 \) such that, from (i) and (ii) in the theorem,
\[
(n+1) \Theta^{(n)} \leq M_6, M_{n+1},
\]
from (4.15) we can obtain
\[
E[I_{n+1} | \xi^n, \alpha^n] \leq \left[ 1 + \left( \frac{1}{n+1} \right)^2 I_n + \left( \frac{1}{n+1} \right)^2 (2K_{n+1}^m + 4M_2) + 2 \left( \frac{1}{n+1} \right) M_1 M_2 K h_{n+1} + 2 \left( \frac{1}{n+1} \right) M_1 M_2 K h_{n+1} + 2 M_4 M_{n+1} \right]^{(n+1) \Theta^{(n)}}.
\]
Therefore, letting \( U_n = V_n = I_n, \mu_n = (n+1)^{-2} \) and
\[
\zeta_n = \left( \frac{1}{n+1} \right)^2 (2K_{n+1}^m + 4M_2) + 2 \left( \frac{1}{n+1} \right) M_1 (M_0 + M_2) K h_{n+1} + 2 M_4 M_{n+1}
\]
in (4.16) and using Lemma 1, it follows that
\[
P[\lim_{n \to \infty} I_n = 0] = 1 \quad \text{and} \quad \lim_{n \to \infty} E[I^p_n] = 0 \quad \text{for all} \quad 0 < \beta < 1.
\]

**Theorem 4.2.** Let \( \{D_n(x|\xi^n, \alpha^n)\}_{n=1}^\infty \) be a sequence of the decision functions obtained by the above argument such that
\[
P[\lim_{n \to \infty} \int [D_n(x|\xi^n, \alpha^n) - D_0^{(n)}(x|\alpha^{n-1})]^3 \, dx = 0] = 1.
\]
Then, it holds that

\[ P\left[ \lim_{n \to \infty} (P_{D_{N\cdot\xi_n,a_n}}(e) - P_{D_{0\cdot\alpha_n-1}}(e)) = 0 \right] = 1, \]

where \( P_{D\cdot\xi}(e) \) is the probability of misclassification using a decision function \( D\cdot\).

**Proof.** Choose \( \varepsilon > 0 \) and then a sufficiently large integer \( N \) such that

\[ P\left[ \left( \int (D_N(x|\xi^N, \alpha^N) - D_0(x|\alpha_N^{-1})) dx \right)^2 \right] < \varepsilon^2/4 \]

where \( B^N \) is a bounded set in \( \mathbb{R}^m \) such that

\[ \int_{B^N} |D_0(x|\alpha_N^{-1})| dx \geq 1 - \varepsilon/2 \]

and \( I_A(x) \) is the indicator of \( A \).

Define sets

\[ H^N = \{ x : D_0(x|\alpha_N^{-1}) \leq 0 \} \]

and

\[ H^N = \{ x : D_N(x|\xi^N, \alpha^N) \geq 0 \} \].

\[ P_{D_0\cdot\alpha_n-1}(e) = q^N(\theta_1|\alpha_N^{-1}) \int f_\theta_1(x) I_{H^N}(x) dx + q^N(\theta_2|\alpha_N^{-1}) \int f_\theta_2(x) I_{H_0^N}(x) dx \]

and

\[ P_{D_{N\cdot\xi_n,a_nN}}(e) = q^N(\theta_1|\alpha_N^{-1}) + \int [-D_0(x|\alpha_N^{-1})] I_{H_0^N}(x) dx \]

Then, from (4.20) and (4.21),

\[ P_{D_{N\cdot\xi_n,a_nN}}(e) - P_{D_{0\cdot\alpha_n-1}}(e) = \int [D_N(x|\xi^N, \alpha^N) - I_{H_N}(x)] I_{B_N}(x) dx \]

where \( B_N^N \) is the complement of set \( B^N \).

It is obvious that

\[ \int [-D_N(x|\xi^N, \alpha^N)] I_{H_0^N}(x) - I_{H_N}(x)] I_{B_N}(x) dx \geq 0. \]

Adding (4.23) to (4.22) and recalling that \( D_0(x|\alpha_N^{-1}) \) is the Bayes decision function, we can obtain that

\[ 0 \leq P_{D_{N\cdot\xi_n,a_nN}}(e) - P_{D_{0\cdot\alpha_n-1}}(e) \]

\[ \leq \int [D_0(x|\alpha_N^{-1}) - D_N(x|\xi^N, \alpha^N)] [I_{H_0^N}(x) - I_{H_N}(x)] I_{B_N}(x) dx \]

\[ + \int [D_0(x|\alpha_N^{-1})] I_{B_N^N}(x) dx \]

\[ \leq \left\{ \int [D_0(x|\alpha_N^{-1}) - D_N(x|\xi^N, \alpha^N)]^2 dx \cdot \int I_{B_N}(x) dx \right\}^{1/2} + \varepsilon/2. \]
Since $\varepsilon$ was arbitrary, the theorem is proved.

§ 5. Learning without a teacher

This section is concerned with the problem of “learning without a teacher” in statistical pattern recognition. We treat the case when there exist $s$ categories $\theta_1, \theta_2, \ldots, \theta_s$, and the case when there can not be assumed a training sequence.

In what follows, it is assumed that, for each instant $n$, the transition probability density function has the following form:

$$p^{(n)}(x^n | \alpha^{n-1}) = \sum_{i=1}^{s} q^{(n)}(\theta_i | \alpha^{n-1}) f^{(n)}_{\theta_i}(x^n),$$

where $\alpha^{n-1} = (\theta_1, \theta_2, \ldots, \theta^{n-1})$ and each $f^{(n)}_{\theta_i}(x^n)$ is defined on $\mathbb{R}^m$.

Now, we consider the problem of finding an algorithm of the estimation of the probabilities $q^{(n)}(\theta_i | \alpha^{n-1})$, $i = 1, 2, \ldots, s$, in the mixture density function $p^{(n)}(x^n | \alpha^{n-1})$, when $f^{(n)}_{\theta_i}(x)$ is known to the observer for every $i$ and $n$, on the basis of the observed but unclassified patterns. Here, we reduce this problem to the problem of finding an algorithm by which, at each instant $n$, we can construct, from the observed patterns, $q^{(n)}_{\theta_i}$, $i = 1, 2, \ldots, s$, which minimizes a quantity defined by

$$I_n = \int \left[ \sum_{i=1}^{s} \left( \hat{q}_i - q^{(n)}(\theta_i | \alpha^{n-1}) \right) f^{(n)}_{\theta_i}(x^n) \right]^2 dx^n + 2\lambda \left( \sum_{i=1}^{s} \hat{q}_i - 1 \right),$$

where $\lambda$ is a Lagrange multiplier.

Differentiating $I_n$ with respect to $\hat{q}_i$, $i = 1, 2, \ldots, s$, and equating the derivatives to zero, we have

$$W^{(n)} Q_n^{(n)}(\alpha^{n-1}) = E[f^{(n)}(x^n) | \alpha^{n-1}] - \lambda U,$$

where $W^{(n)}$ is the matrix with elements $w_{ij}^{(n)} = \int f^{(n)}_{\theta_j}(x) f^{(n)}_{\theta_i}(x) dx$, $i, j = 1, 2, \ldots, s$; $E[f^{(n)}(x^n) | \alpha^{n-1}]$ is a column vector of with the $i$-th component equal to $E[f^{(n)}_{\theta_i}(x^n) | \alpha^{n-1}] = \int f^{(n)}_{\theta_i}(x^n) p^{(n)}(x^n | \alpha^{n-1}) dx^n$, $i = 1, 2, \ldots, s$; $U$ is a column vector of $s$ components all equal to one and $Q_n^{(n)}(\alpha^{n-1})$ is a column vector with the $i$-th component $q^{(n)}_{\theta_i}$, $i = 1, 2, \ldots, s$. When $\det W^{(n)}$, the determinant of $W^{(n)}$, is not equal to zero at each instant $n$, the $i$-th component of $Q_n^{(n)}(\alpha^{n-1})$ which satisfies (5.3) is

$$q^{(n)}_{\theta_i} = \frac{\sum_{k=1}^{s} \sum_{j=1}^{j} E[f^{(n)}_{\theta_k}(x^n) | \alpha^{n-1}] W_{jk}^{R(n)} W_{ji}^{R(n)} - \det W^{(n)}}{\det W^{(n)}} W_{ji}^{R(n)} f^{(n)}_{\theta_i}(x^n),$$

where $W^{R(n)}$ is the adjunct of $w^{(n)}_{ij}$ in the matrix $W^{(n)}$. Then, we can write (5.4) to the following form:

$$q^{(n)}_{\theta_i} = E[f^{(n)}(x^n) | \alpha^{n-1}],$$

where
In view of the above argument, we shall construct the following algorithm with a sequence of non-negative real numbers \( \{ \gamma_n \}_{n=1}^{\infty} \) such that

\[
\sum_{n=1}^{\infty} \gamma_n = \infty \quad \text{and} \quad \sum_{n=1}^{\infty} \gamma_n^2 < \infty.
\]

Firstly, using an observed but unclassified pattern \( x^1 \) at instant 1, we make for \( i = 1, 2, \ldots, s \)

\[
g^{(0)}(\xi^1, \alpha^1) = g^{(0)} - \gamma_1 [F^{(0)}(x^1) - g^{(0)}],
\]

where \( g^{(0)} = 0 \) for all \( i \).

Secondly, using an observed but unclassified pattern \( x^2 \) at instant 2, we make for \( i = 1, 2, \ldots, s \)

\[
g^{(0)}(\xi^2, \alpha^2) = g^{(0)}(\xi^1, \alpha^2) + \gamma_2 [F^{(0)}(x^2) - g^{(0)}(\xi^1, \alpha^2)].
\]

In general, using an observed but unclassified pattern \( x^{n+1} \) at instant \( n+1 \), we make for \( i = 1, 2, \ldots, s \)

\[
g^{(n+1)}(\xi^{n+1}, \alpha^{n+1}) = g^{(0)}(\xi^n, \alpha^n) + \gamma_{n+1} [F^{(n+1)}(x^{n+1}) - g^{(0)}(\xi^n, \alpha^n)].
\]

Then, we can prove the following theorem concerning \( g^{(n+1)}(\xi^{n+1}, \alpha^{n+1}) \) and \( q^{(n+1)} \).

**THEOREM 5.1.** Let the following hypotheses be satisfied:

(i) for each instant \( n \), \( \det W^{(n)} \) is not equal to zero,

(ii) there exist a set of positive numbers \( \{ q_i \}_{i=1}^{s} \) (0 \( \leq q_i \leq 1 \), \( \sum_{i=1}^{s} q_i = 1 \)) and a sequence of positive numbers \( \{ M_n \}_{n=1}^{\infty} \) such that, for all \( i \),

\[
\gamma_n [q^{(n)}(\xi^n, \alpha^n) - q_i]^2 \leq M_n
\]

and such that \( \sum_{n=1}^{\infty} M_n < \infty \).

(iii) \( \{ f_{ij}(x) \}_{i=1}^{s} \) is a set of the conditional probability density functions defined on \( \mathbb{R}^m \) and satisfying \( \int f_{ij}(x) f_{ij}(x) dx < \infty \), for \( i, j = 1, 2, \ldots, s \).

(iv) there exists a sequence of positive numbers \( \{ N_n \}_{n=1}^{\infty} \) such that, for each \( n \),

\[
\gamma_n^{-1} \left( \int f_{ij}(x) f_{ij}(x) dx - \int f_{ij}(x) f_{ij}(x) dx \right)^2 \leq N_n
\]

and such that \( \sum_{n=1}^{\infty} N_n < \infty \).

Then, it holds that, for all \( i \),

\[
P \lim_{n \to \infty} u^{(n)} = 0 \quad \text{and} \quad \lim_{n \to \infty} E[u^{(n)}] = 0 \quad \text{for all} \ 0 < \beta \leq 1,
\]

where \( u^{(n)} = g^{(n)}(\xi^n, \alpha^n) - q^{(n)} \).

**PROOF.** By the construction \( g^{(n+1)}(\xi^{n+1}, \alpha^{n+1}) \), \( i = 1, 2, \ldots, s \), we have
The equality (5.10) can be written in terms of \( u_{i}^{(n+1)} \), \( u_{i}^{(n)} \) and \( \theta_{i}^{(n)} \) as

\[
(5.11) \quad u_{i}^{(n+1)} = (1 - \gamma_{n+1})u_{i}^{(n)} + (1 - \gamma_{n+1})\theta_{i}^{(n)} + \gamma_{n+1}[F_{i}^{(n+1)}(x_{n+1}) - q_{i}^{(n+1)}],
\]

where \( \theta_{i}^{(n)} = q_{i}^{(n)} - q_{i}^{(n+1)} \).

Square both sides of (5.11) and then taking conditional expectation, we can obtain, for all \( i \) and a sufficiently large \( n \),

\[
E[(u_{i}^{(n+1)})^2 | \xi^{n}, \alpha^{n}] \leq (1 - \gamma_{n+1})^2 (u_{i}^{(n)})^2 + (1 - \gamma_{n+1})^2 (\theta_{i}^{(n)})^2 + 2(1 - \gamma_{n+1}) | u_{i}^{(n)} | | \theta_{i}^{(n)} | + \gamma_{n+1} \sigma^2,
\]

where the positive number \( \sigma^2 \) satisfies a condition \( \text{Var} [F_{i}^{(n+1)}(x_{n+1}) | \alpha^{n}] \leq \sigma^2 \). Noting that, for \( i = 1, 2, 3, \ldots, s \) and all \( n \),

\[
2 | u_{i}^{(n)} | | \theta_{i}^{(n)} | \leq \gamma_{n+1}(u_{i}^{(n)})^2 + \gamma_{n+1}^{-1}(\theta_{i}^{(n)})^2,
\]

from (5.12) we have for all \( i \);

\[
E[(u_{i}^{(n+1)})^2 | \xi^{n}, \alpha^{n}] \leq (1 - \gamma_{n+1})^2 (u_{i}^{(n)})^2 + (1 - \gamma_{n+1})^2 (\theta_{i}^{(n)})^2 + 2(1 - \gamma_{n+1}) | u_{i}^{(n)} | | \theta_{i}^{(n)} | + \gamma_{n+1} \sigma^2.
\]

Then, from (ii), (iii) and (iv), there exists a positive number \( M \) such that

\[
(5.14) \quad \gamma_{n+1}(\theta_{i}^{(n)})^2 + (\theta_{i}^{(n)})^2 \leq MM_n.
\]

From (5.14), we can write (5.13) to the following form:

\[
(5.15) \quad E[(u_{i}^{(n+1)})^2 | \xi^{n}, \alpha^{n}] \leq (1 + \gamma_{n+1})(u_{i}^{(n)})^2 + \gamma_{n+1}(u_{i}^{(n)})^2 + (\theta_{i}^{(n)})^2 + \gamma_{n+1} \sigma^2.
\]

Therefore, by Lemma 1, it follows that, for all \( i \),

\[
P[\lim_{n \to \infty} u_{i}^{(n)} = 0] = 1 \quad \text{and} \quad \lim_{n \to \infty} E[(u_{i}^{(n)})^2] = 0 \quad \text{for all} \ 0 < \beta < 1.
\]

Also, taking the unconditional expectation on both sides of (5.15) and using Lemma 2, it follows that, for all \( i \),

\[
\lim_{n \to \infty} E[(u_{i}^{(n)})^2] = 0.
\]

Thus, the proof of the theorem is completed.

Next, we have the following theorem concerning the order of mean convergence.

**Theorem 5.2.** Let the following hypotheses be satisfied:

(i) \( \gamma_n = a/n^\alpha, \ a > 0, \ (1/2) < \alpha < 1 \),

(ii) \( \text{Var} [F_{i}^{(n)}(x_{n}) | \alpha^{n-1}] \leq \sigma^2 \) for all \( i \) and \( n \),

(iii) \( E[(\theta_{i}^{(n)})^2] = O(n^{-\omega}), \ \omega > \alpha, \ \text{for all} \ i \).

Then, it holds that

\[
E[(u_{i}^{(n)})^2] = \begin{cases} O(n^{-(3\omega-\alpha)}) & \text{if} \ \omega < (3/2)\alpha \\ O(n^{-\alpha}) & \text{if} \ \omega \geq (3/2)\alpha, \end{cases}
\]

where the notation \( f(n) = O(g(n)) \) means \( \limsup_{n \to \infty} |f(n)/g(n)| < \infty \).
PROOF. By (i), (ii), (iii) and (5.13), there exist a positive integer $N$ and three positive numbers $C_1, C_2, C_3$ such that, for all $n \geq N$,
\begin{equation}
E[(u_i^{(n+1)})^2] \leq (1-C_1/n^a)E[(u_i^{(n)})^2] + C_2/n^2 + C_3/n^{3a-\alpha}.
\end{equation}
Consequently, we can obtain for $\omega < (3/2)a$
\begin{equation}
E[(u_i^{(n+1)})^2] \leq (1-C_1/n^a)E[(u_i^{(n)})^2] + C_4/n^b,
\end{equation}
and for $\omega \geq (3/2)a$
\begin{equation}
E[(u_i^{(n+1)})^2] \leq (1-C_1/n^a)E[(u_i^{(n)})^2] + C_5/n^2,
\end{equation}
where $C_4$ and $C_5$ are some positive numbers.
Thus, an application of Lemma 3 for $a_n = E[(u_i^{(n)})^2]$ gives us the result of the theorem.

§ 6. Acknowledgement

The author is deeply indebted to Professor T. Kitagawa for his valuable advices. The author is also grateful to Professors S. Kanô and N. Furukawa for their advices and encouragements.
