The Fourier Coefficients and the Singular Moduli of the Elliptic Modular Function $j(\tau)$

Masanobu Kaneko

(Received August 1, 1995; Accepted September 1, 1995)

Abstract

We shall give a closed formula for the Fourier coefficients of the elliptic modular function $j(\tau)$ expressed in terms of singular moduli, i.e., the values at imaginary quadratic arguments. The formula is a consequence of a theorem of D. Zagier which is intimately related to a recent result of R. Borcherds on a construction of modular forms as infinite products.

Key Words: Elliptic modular function; Fourier coefficients; complex multiplication; modular forms of half integral weight.

1. Introduction

The elliptic modular function $j(\tau)$, often referred to as the modular invariant, enjoys many beautiful properties. In particular, each singular modulus, i.e., the value at an imaginary quadratic argument (a CM point), is algebraic and generates a certain abelian extension called the ring class field over the imaginary quadratic field of the argument. On the other hand, the Fourier coefficients of $j(\tau)$ have a mysterious connection with the degrees of irreducible representations of the largest sporadic simple group "Monster"; this connection is known as (a part of) the "moonshine", which was established by R. Borcherds.

Since CM points are dense in the complex upper half-plane $\mathcal{H}$, the domain of definition of the $j$-function, $j(\tau)$ as an analytic (or even continuous) function is completely determined by its values at such points. It would therefore not be unreasonable to expect a formula for the Fourier coefficients of $j(\tau)$ expressed in terms of the singular moduli. The aim of the present paper is to show that there indeed exists such a formula. A different kind of exact formula for the Fourier coefficients of $j(\tau)$ has been known since H. Petersson and H. Rademacher, which expresses the coefficients by an infinite series involving a Kloosterman sum and the modified Bessel function of the first kind. Their formula is, it is said, analytical, whereas ours is essentially arithmetical.

The idea of explaining the moonshine via complex multiplication theory might thus not be sheer nonsense.
2. Theorem

The elliptic modular function $j(\tau)$ is invariant under the action of the modular group $SL_2(\mathbb{Z})$; in particular, it has a Fourier series expansion:

$$j(\tau) = \frac{1}{q} + 744 + \sum_{n=1}^{\infty} c_n q^n \quad (q = e^{2\pi i \tau}, \ \tau \in \mathbb{H}),$$

the first few coefficients being $c_1 = 196884$, $c_2 = 21493760$, $c_3 = 864299970$, ...; all the $c_n$ are positive integers.

After D. Zagier, we define for each natural number $d > 0$, $d \equiv 0, 3 \pmod{4}$, an integer $J_1(d)$ by

$$J_1(d) = \sum_{\omega \in \mathbb{Z}} \frac{2}{\omega} \sum_{[\omega_0]} (j(\omega_0) - 744),$$

where the first sum runs over all imaginary quadratic orders $\mathbb{O}$ that contain the order $\mathbb{O}_d$ of discriminant $-d$, $\omega_0$ is the number of units in $\mathbb{O}$, and the second sum is over a representative of the proper $\mathbb{O}$-ideal class. Note that here $j(\tau)$ is viewed in the standard manner as a function on the equivalence classes of lattices in $\mathbb{C}$. In addition, we set

$$J_1(0) = 2, \ J_1(-1) = -1 \ \text{and} \ J_1(d) = 0 \ \text{for} \ d < -1 \ \text{or} \ d \equiv 1, 2 \pmod{4}.$$

That $J_1(d)$ is in fact an integer will be explained in remark 3) after the theorem. Our formula is then given as

**Theorem.** For any $n \geq 1$,

$$c_n = \frac{1}{n} \left\{ \sum_{r \in \mathbb{Z}} J_1(n-r^2) + \sum_{r \geq 1, \ \text{odd}} ((-1)^{n} J_1(4n-r^2) - J_1(16n-r^2)) \right\}.$$

**Examples.**

$$c_1 = 2J_1(0) - J_1(3) - J_1(15) - J_1(7)$$

$$= 2 \times 2 - (-248) - (-192513) - (-4119)$$

$$= 196884.$$

$$c_2 = \frac{1}{2} (J_1(7) + J_1(-1) - J_1(31) - J_1(23) - J_1(7))$$

$$= (J_1(-1) - J_1(31) - J_1(23))/2$$

$$= (-1 - (-39493539) - (-3493982))/2$$

$$= 21493760.$$

Several remarks are in order:

1) Each sum in the formula is finite.
2) By using relation (3) in the next section, the formula can also be written as

$$c_n = \frac{1}{n} \sum_{r \in \mathbb{Z}} \left\{ J_1(n-r^2) - \frac{(-1)^{n+r}}{4} J_1(4n-r^2) + \frac{(-1)^r}{4} J_1(16n-r^2) \right\}.$$ (1)
3) As is well known in the theory of complex multiplication, the sum \( \sum \alpha_{\mathfrak{O}} \left( j(\alpha) - 744 \right) \) in the definition of \( J_1(d) \) is the (absolute) trace of the algebraic integer \( j(\mathfrak{O}) - 744 \), from which it follows that the summand \( \frac{2}{\omega \mathfrak{O}} \sum \alpha_{\mathfrak{O}} \left( j(\alpha) - 744 \right) \) is an integer if \( \mathfrak{O} \neq \mathfrak{O}_3, \mathfrak{O}_4 \), while the well known values \( j(\mathfrak{O}_3) = 0, j(\mathfrak{O}_4) = 1728 \), as well as \( \omega \mathfrak{O}_3 = 6, \omega \mathfrak{O}_4 = 4 \), and that the class numbers of \( \mathfrak{O}_3 \) and \( \mathfrak{O}_4 \) are 1, give \( \frac{2}{\omega \mathfrak{O}} \sum \alpha_{\mathfrak{O}} \left( j(\alpha) - 744 \right) = -248, 492 \) for \( \mathfrak{O} = \mathfrak{O}_3, \mathfrak{O}_4 \), respectively. Hence \( J_1(d) \) is always a rational integer. Values of \( J_1(d) \) up to \( d = 100 \) are given in the table at the end of the paper.

4) The \( J_1(d) \)'s can be calculated recursively and elementarily (without knowing anything about complex multiplication) by

\[
J_1(4n-1) = -a_n - \sum_{2 \leq r \leq \sqrt{4n+1}} r^2 J_1(4n-r^2),
\]

\[
J_1(4n) = -2 \sum_{1 \leq r \leq \sqrt{4n+1}} J_1(4n-r^2)
\]

for \( n \geq 0 \), where \( a_0 = 1, a_n = 240 \sum_{d | n} d^3 \) \((n \geq 1)\), and an empty sum is understood to be 0. This is due to D. Zagier (see the next section).

5) In the language of binary quadratic forms, the definition of \( J_1(d) \) reads as follows:

\[
J_1(d) = \sum_{[\mathcal{Q}] \in \text{SL}_2(\mathbb{Z}) - \text{equivalence classes of integral, not necessarily primitive, positive-definite quadratic forms of discriminant} - d} \frac{2}{|\text{Aut}(\mathcal{Q})|} \left( j(\alpha_{\mathcal{Q}}) - 744 \right),
\]

where the sum is over a set of representatives of the \( \text{SL}_2(\mathbb{Z}) \)-equivalence classes of integral, not necessarily primitive, positive-definite quadratic forms of discriminant \(-d\), \( |\text{Aut}(\mathcal{Q})| \) denotes the order of the automorphism group of \( \mathcal{Q} \) in \( \text{SL}_2(\mathbb{Z}) \), and \( \alpha_{\mathcal{Q}} \) is the imaginary quadratic irrationality in \( \mathfrak{O} \) that corresponds to \( \mathcal{Q} \).

3. Proof

What is crucial in the proof of the theorem is the following result due to Don Zagier.

Theorem (D. Zagier\(^{5}\)). The series

\[
g_1(\tau) = \sum_{d \equiv -1 \mod 3} J_1(d) q^d
\]

is a modular form of weight \( \frac{3}{2} \) on \( \Gamma_0(4) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}_2(\mathbb{Z}) \mid 4 \mid c \right\} \), holomorphic in \( \mathfrak{O} \) and meromorphic at cusps. Specifically,

\[
g_1(\tau) = -\frac{E_4(\tau) \theta_1(\tau)}{\eta(4 \tau)^6}.
\]

where \( E_4(\tau) = \sum_{n=0}^{\infty} a_n q^n \) is the normalized Eisenstein series of weight 4 (\( a_n \) being as in the preceding remark 4), \( \eta(\tau) = q^{1/24} \prod_{n=1}^{\infty} (1 - q^n) \) is the Dedekind eta function, and \( \theta_1(\tau) = \sum_{n \in \mathbb{Z}} (-1)^n q^{n^2} \) is one of the standard theta series of Jacobi.

He proved this by showing...
\[ \sum_{r \in \mathbb{Z}} J_1(4n - r^2) = 0 \quad n \geq 0 \quad (3) \]

and
\[ \sum_{r \in \mathbb{Z}} (n - r^2) J_1(4n - r^2) = 2a_n \quad n \geq 0. \quad (4) \]

Since it is easy to check that the coefficients of the expression on the right-hand side of (2) satisfy the same recursions, and since the recursions clearly determine the coefficients uniquely, this proves (2) and hence the theorem. (See the book of Eichler-Zagier\(^3\) for these kinds of recursions and a connection with the theory of Jacobi forms.) The relations (3) and (4) were deduced from a classical formula on the diagonal of the Kronecker modular equation and from a similar formula of M. Eichler. See the forthcoming paper by Zagier\(^6\) for the details and also for the discussion on the relation to a theorem of R. Borcherds\(^2\).

By virtue of this theorem, we can unify our formula, or rather the equivalent formula (1), into an identity between modular forms (of weight 2) as
\[ \frac{1}{2\pi i} \frac{d}{d\tau} j(\tau) = g_1(\tau) \theta_0(\tau) - \frac{1}{4} (\langle g_1 \theta_1 \rangle) U_4(\tau + \frac{1}{2}) + \frac{1}{4} (\langle g_1 \theta_1 \rangle | U_4^2)(\tau), \]

where \( \theta_0(\tau) = \sum_{n \in \mathbb{Z}} q^n \), and \( U_4 \) is the operator \( \sum b_n q^n \mapsto \sum b_{4n} q^n \), which, as well as the translation \( \tau \mapsto \tau + \frac{1}{2} \), sends a modular form to a modular form of the same weight (but possibly on a different group). Hence, owing to the finite-dimensionality of the space of modular forms of a given weight and a group holomorphic except possible poles of bounded order at cusps, the equality holds if the first several Fourier coefficients coincide, which is indeed the case and thereby completes the proof of our theorem.

Incidentally, the relations (3) and (4) give us a formula for quick and elementary calculation of \( J_1(d) \), as already mentioned in the preceding section; we can also calculate \( J_1(d) \) by (2) or by the following formulas:
\[ \sum_{d \geq 0, \equiv 0 \pmod{4}} J_1(d) q^{d/4} = 2 \frac{E_4(\tau)}{\theta_0(\tau) \theta_1(\tau)}, \]
\[ \sum_{d \geq -1, \equiv 3 \pmod{4}} J_1(d) q^{d/4} = -2 \frac{E_4(\tau)}{\theta_2(\tau) \theta_1(\tau)}, \]

where \( \theta_2(\tau) = \sum_{n \in \mathbb{Z}} q^{(n+\frac{\tau}{2})^2} \) is the other standard theta series of Jacobi.

A more “natural” proof of the theorem is provided by taking account of the action of the Hecke operators. Specifically, an argument like the one used to prove (3) shows that
\[ \sum_{r \in \mathbb{Z}} J_2(4n - r^2) = 2nc_n \quad (n \geq 0), \quad (6) \]

where, in general, we define
\[ J_m(d) = \sum_{0 \geq 0 \equiv \omega \pmod{\omega}} \sum_{[a, \omega]} ((d - 44) | T_m(a \omega)) (T_m: \text{the Hecke operator of weight 0}) \]

for any \( m \geq 1 \). The relation (6) is then transformed into our theorem using the relations.
Fourier Coefficients of the Elliptic Modular Function $j(\tau)$

$$J_2(d) = J_1(4d) + \left( -\frac{d}{2} \right) J_1(d) + 2J_1\left( \frac{d}{4} \right)$$  \hspace{1cm} (7)

and (3), where $\left( -\frac{d}{2} \right)$ is Kronecker's symbol and $J_1\left( \frac{d}{4} \right) = 0$ if $\frac{d}{4}$ is not an integer. The relation (7) and the similar ones for $J_m(d)$ can be interpreted as saying that the Hecke actions on $g_1(\tau)$ and on $j(\tau)$ are compatible, as discussed in Zagier$^6$.

Acknowledgment

This paper orginated from the work of Don Zagier, who showed it to me during my stay at the Max-Planck-Institut at Bonn, Germany, in 1994. My warmest gratitude goes to him for explaining his beautiful result to me. I would also like to take this opportunity to thank Prof. Friedrich Hirzebruch and Ms. Silke Suter, to whom I owe much for my pleasant stay at the Institute.
