Introduction

Chemical Mechanical Polishing (CMP) is investigated or used for the dielectric planarization and tungsten plug formation. In our prior work, we formed a tungsten plug using the newly developed MnO₂ slurry [1]. In this study, we tried to planarize a dielectric (SiO₂) with MnO₂ slurry for the first time. For dielectric planarization, wide feature planarization and minimal lower level dielectric removal is essential and colloidal silica slurry is widely used [2]. We found that MnO₂ slurry can planarize wide feature (2 mm x 2 mm) steps to a smaller height than the conventional slurry, while incurring less lower level dielectric removal.

Experiment

For both MnO₂ slurry and the conventional colloidal silica slurry, we examined polishing rates and the planarization ability. Figure 1 shows the polishing conditions. The speed of the head rotation is the same with that of the turntable throughout the experiments. We varied the polishing pressure from 0.21 kg/cm² to 0.84 kg/cm² and the rotation speed from 20 to 100 rpm. The average abrasive particle size of MnO₂ was about 0.1 μ m. The MnO₂ solid concentration was 7 wt%.

We formed a 0.5 μ m thick SiO₂ film on the six inch Si wafer by wet oxidation (Figure 2) and polished to characterize the polishing rate. Figure 3 shows a schematic cross-section of the test structure used to characterize the planarization ability. The SiO₂ film is formed using TEOS. Each region is 2 mm square and the initial step height is 0.8 μ m. We measured the remaining thickness of the high (T_H) and the low (T_L) and calculated the step height (=T_H - T_L).

Results and Discussion

We examined the pressure dependence of the polishing rate with MnO₂ slurry and the conventional slurry which is widely used. Figure 4 shows that MnO₂ has higher polishing rate at below 0.7 kg/cm² than the conventional slurry.

We examined the rotation speed dependence of the polishing rate at pressures

0.56 kg/ cm² and 0.21 kg/ cm², respectively. At 0.56 kg/ cm², the polishing rate of both slurries increased for higher rotation speeds (Figure 5). At 0.21 kg/ cm², the polishing rate of MnO₂ slurry increased for higher rotation speeds, whereas the polishing rate of the conventional slurry did not (Figure 6).

At a pressure of 0.21 kg/ cm², MnO₂ slurry planarizes a 2 mm x 2 mm region step to a height of less than 0.1 um after 5 minutes of polishing. The conventional slurry planarizes the step to a height of over 0.35 um after 12 minutes of polishing. This is because the conventional slurry cannot achieve a sufficient removal rate at 0.21 kg/ cm² pressure (Figure 7). Despite the lower pressure, the upper level is more selectively removed [3], the conventional slurry cannot be used appropriately at 0.21 kg/ cm².

Therefore, we planarized the step at 0.21 kg/ cm² with MnO₂ and 0.56 kg/ cm² with the conventional slurry. We controlled the rotation speed to get the same polishing rate (120 nm/min). Figure 8 shows that the step height decreases and the lower level oxide removal increases as the polishing time increases. However, MnO₂ slurry reduces the step height faster and the final step height is less than the conventional slurry. To clarify the planarization efficiency, we plotted the relationship between the step height and the lower level oxide removal of both slurries (Figure 9). MnO₂ slurry can reduce the step height with less lower level oxide removal. Moreover, it can achieve a smaller height.

Figure 10 shows an SEM image of the planarized dielectric after MnO₂ polish applied to interconnect pattern. A completely planarized surface is achieved. We also developed the cleaning method for post MnO₂ polish (Figure 11). We can get the same level of cleanness with the reference by adding the HCl+H₂O₂+ H₂O (1:1:48) solution (at RT) supply before scrubbing.

Conclusion

We used the MnO₂ slurry for the dielectric planarization. We found that MnO₂ slurry has an ample removal rate at a low polishing pressure, whereas the conventional slurry does not. Therefore, the MnO₂ slurry can planarize dielectric more completely, with less lower level removal than the conventional slurry.
