Key to families, subfamilies, tribes and genera of the superfamily Curculionoidea of Japan excluding Scolytidae, Platypodidae and Cossoninae

(Comparative morphology, phylogeny and systematics of the superfamily Curculionoidea of Japan. III)

Katsura Morimoto

In this paper a key to families, subfamilies, tribes and genera of the superfamily Curculionoidea excluding Scolytidae, Platypodidae and Cossoninae is given. Scolytidae and Platypodidae have been studied by Dr. Jozo Murayama and Mr. Akira Nobuchi, and the revision of the subfamily Cossoninae will be published before long by Dr. Masayasu Konishi.

I acknowledge my indebtness to the late Prof. Teiso Esaki, Prof. Keizô Yasumatsu and Prof. Yoshihiro Hirashima for their kind guidance in the course of the present study.

To Prof. Toichi Uchida and Prof. Chihisa Watanabe, of Hokkaido University, I am much indebted to the examination of the type specimens described by Dr. Hiromichi Kôno.

Key to families of Curculionoidea of Japan.

- 1'. Maxillary palpi 3-segmented. Maxillary lacinia very often indistinct. Mandibles move more or less obliquely. Penis with the dorsal plate much narrower than the ventral one or the dorsal

Contribution Ser. 2, No. 138. Entomological Laboratory, Kyushu University.

	plate absent. Cap-piece of tegmen bilobed or vestigial. Antennae often geniculate. Preoral cavity without a transverse wall or
	bridge. Ovary with 1—2 pairs of ovarioles
2.	Labrum distinct and separated. Preoral cavity completely divided
	by a transverse wall. Labial and maxillary palpi normal, flexible.
	Tentorial bridge incomplete, posterior arms reduced to a pair of
	small processes and originated from postoccipital suture. Elytral
	epipleura invisible from sides. Testis with 1 2 pairs of accessory
	glands. Ovipositor with styli strongly sclerotized and toothed
	coxites deeply inflected inwards from above. Female with 9th
	abdominal tergite
2'.	
	flexible. Preoral cavity with a transverse bridge connecting the
	pregenal areas (Attelabinae) or the bridge absent (Rhynchitinae).
	Tentorium with the posterior arms broad, originated from the
	gular suture and ventral parts of postoccipital suture. Elytral
	epipleura freely visible from sides. Testis with 3 or more paired
	accessory glands. Ovipositor normal or vestigialAttelabidae
3.	Postcoila shallow, located on the anterior margin of postgenal
	area, into which the ball of postartis of mandible fits not strongly.
	Maxillae move nearly in horizontal plane. Head never produced
	into a rostrum or with a very short rostrum. Tentorium with
	the posterior arm very broad, originated from postoccipital, gular
	and hypostomal sutures. Ovipositor vestigial4
3′.	
	anterior margin, into which the ball of postartis of mandible fits
	strongly. Maxillae move vertically. Head more or less produced
	into a rostrum. Tentorium with the posterior arms originated
	from postoccipital and gular sutures. Ovipositor always present
a	5
4,	Anterior tarsi with the 1st segment longer than the 3 followings
	taken together. Abdomen with the 3rd—7th segments freely articulated the desired to the segments.
	lated to each other, 9th sternite absent in male. Penis without
4'.	apophysis. Maxillary lacinia distinct
.3 *	abdomen with the 3rd and 4th sternites connate, 5th—7th segments
	similarly articulated to each other, 9th sternite present in male.
	Penis with a pair of apophysis. Maxillary lacinia indistinct
	Scolytidae
5.	Prementum normal, freely visible from ventral side. Antennae
	with club segmented, closely pubescent. Penis with the ventral
	plate not incised. Posterior part of ventriculus furnished with
	several gastric caecae. Pygidium formed of 8th tergite in male
	6

- 5'. Prementum very small, deeply retracted into the oral cavity and invisible from ventral side. Penis with the ventral plate incised. Ventriculus furnished with short gastric caecae on entire external surface. Antennae with the 1st segment of club glossy, the other segment of club rigid and closely pubescent, funicle 4—6 segmented. Pygidium formed of 7th tergite in maleRhynchophoridae
- 6. Proventriculus not developed, with 8 or 16 rows of setae. Penis with dorsal and ventral plates, cap-piece of tegmen large, bilobed, often articulated to the basal piece, apical part of cap-piece setose
- 6'. Proventriculus well developed, with 8 paires of the row of bladelike plates. Penis with the ventral plate only, dorsal plate absent, cap-piece of tegmen less developed, often absentCurculionidae

Family Anthribidae

As many genera of the Anthribidae remain undissected, I can not answer the question of the phylogeny at present. Following key is given as a preliminary step towards a revision of the Anthribidae from Japan.

Key to the subfamilies of the Anthribidae.

- 1. Antennae inserted on the dorsal surface of rostrum or head

 Choraginae
- 1'. Antennae inserted on the lateral surface of rostrum ... Anthribinae

Subfamily Choraginae

Key to genera.

- 2. Eyes rounded, the upper edges not closer together than the lower

- First segment of front tarsi longer than the followings taken together. Pygidium nearly as long as wide... Araecerus Schönherr
- 4'. First segment of front tarsi shorter than the followings taken

	beak-like manner
5.	Antennae very long, filiform, much longer than body in female
556	and 4-5 times as long as body in male
5 ′ .	Antennae shorter than body. Elytra with humeri a little narrower
	than pronotum and rounded
	Subfamily Anthribinae
	Key to genera.
1.	Dorsal prothoracic carina basal
1'.	Dorsal prothoracic carina antebasal8
2-	Rostrum strongly carinate on each side and the carinae contiguous
	with eyes respectively. Rostrum very short, rapidly narrowing
o.t	anteriorly3
2'.	Rostrum parallel-sided, not carinate on each side
3.	Eyes convex, suboval. Lateral carinae of rostrum reaching the anterior margin of eyes respectively. Frons between eyes nearly
	as broad as the apex of rostrum
3'.	Eyes more or less convergent on frons. Lateral carinae of rostrum
	prolonged posteriorly to the middle of eyes respectively. Frons
	between eyes narrower than rostrumParamesus Fahraeus
4.	Fourth segment of antennae abnormally large in male. Antennae
	inserted on the dorso-lateral surface of rostrum. Rostrum ex-
	tremely short. Antennal scrobes contiguous with eyes. Body
	cylindrical
4'.	Antennae normal
5.	Eyes convex, suboval. Postmentum strongly constricted towards the base
5'.	Eyes emarginate. Postmentum not strongly constricted6
6.	Antennal scrobes sulciform, prolonged downards. Antennae short,
	widened apically from the 4th segment. Body parallel-sided
6'.	Antennal scrobes foveiform. Antennae longer than body in male,
	normally clubbed
7.	$Antennae\ inserted\ on\ the\ dorso-lateral\ surface\ of\ rostrum,\ antennal$
	scrobes contiguous with eyes. Eyes very strongly emarginate.
	Rostrum extremely short
7'.	Antennae inserted on the lateral surface of rostrum, antennal
	scrobes separated from eyes. Eyes strongly emerginate. Rostrum,
8.	as long as wide
0.	ventral surface of rostrum9
8'.	Antennal scrobes foveiform, lateral

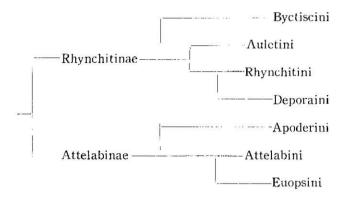

9.	Rostrum perpendicular to the axis of body. Dorsal prothoracic carina curving forwards on each side. Lateral prothoracic carina
9′.	absent. Antennal scrobes shallower
10.	Lateral prothoracic carina prolonged anteriorly from the base to the middle. Dorsal prothoracic carina subparallel to the base of pronotum. Third tarsal segment normal. Body elongate-oval Asemorhinus Sharp
10'.	Lateral prothoracic carina developed in entire length of pronotum. Dorsal prothoracic carina curving forwards to the sides. Third tarsal segment small, retracted into the anterior cavity of the 2nd segment. Body parallel-sided
11.	Eyes emarginate. Antennal scrobes lateral or dorso-lateral, partly visible from above
11'.	Eyes round
12.	Antennae filiform, very slender, 3—4 times as long as body in male and much longer than body in female. Small species
12'.	Antennae very robust, shorter than body. Large species
13.	Pronotum with a horseshore-shaped deep depression
13'.	Pronotum simple
14.	Antennal scrobes latero-dorsal. Rostrum suddenly dilated before
	the middle, with a deep median longitudinal sulcus. Male and
	tennae 2-3 times as long as body. Large species
14'.	Antennal scrobes latero-ventral, invisible from above
15.	Dorsal prothoracic carina close to the posterior margin, bisinuate
	each side of the carina very close to the hind angle of pronotum
	lateral carina very short. Hind angle of pronotum narrower than
15/	90°. Small species
15'.	Hind angle of pronotum nearly rectangular. Dorsal prothoracic carina more or less remote from the posterior margin
16.	Prothorax strongly narrowed behind dorsal carina so as to leave
	a deep excision between it and elytra. First segment of front
	tarsi a little longer than the followings taken together
16'.	Prothorax normally narrowed behind dorsal carina19
17.	Each side of male head expanded into a process bearing eye.
	Female from between eyes as broad as rostrum
17′.	Frons between eyes much narrower than rostrum
18.	Elytra without nodules. Tarsi with the 1st segment slender, nearly

as long as the remaining segments taken together
Elytra nodulosus. Tarsi broader, 1st segment a little shorter than
the remaining segments taken together
Directarius Jordan, Dissoleucas Jordan
Rostrum separated from head by a transverse sulcus on the ventral
surface, perpendicular to the axis of bodyTropideres Schönherr
Rostrum oblique to the axis of body, not separated from head by
a sulcus
Eyes lateral, strongly convex. Frons between eyes a little narrower
than rostrum. Antennal club normal Autotropis Jordan
Eyes weakly convex, more or less convergent to each other on
frons
Dorsal prothoracic carina curved anteriorly on each side. Antennae
with club slender, loosely articulated
Dorsal prothoracic carina rectangular on each side
Dorsal prothoracic carina close to the base. Antennae with club
slender, loosely articulated. Rostrum weakly laminate on each
side above antennal scrobe, undersurface simple Hypseus Pascoe
Dorsal prothoracic carina remote from the base. Rostrum strongly
laminate on each side above antennal scrobe, with a pair of foveae
near the lower end of antennal scrobe. Antennae with club
normal

Family Attelabidae

Family Attelabidae was divided by many authorities such as Voss, Ter-Minasyan, Kôno, etc., into three subfamilies, Attelabinae, Apoderinae and Rhynchitinae. I came to the similar conclusion that it may be better to divide the Attelabidae into two subfamilies, Attelabinae and Rhynchitinae from the point of comparative morphology as already be pointed out by Crowson. Apoderinae auct. and Attelabinae auct. are very close to each other in many characters excepting the constricted head and the shape of tentorium. Euopsini is a distinct tribe and separable from Apoderini and Attelabini by the large eyes and absence of labial palpi. Attelabini should be inferred the most primitive tribe among Attelabinae from the structures of prementum. Apoderini (Apoderinae of many authors) is very uniform in various characters. Subtribe Eugnamptina was treated by Voss under the tribe Rhynchitini and Ter-Minasyan transfered it into the tribe Deporaini. I agree with the treatment of Ter-Minasyan as noted in the following key.

The relationship of the tribes of Attelabidae may be illustrated as follows:

Key to subfamilies.

- Tibiae mucronate in both sexes, uncinate in male, front tibiae serrate on the ventral margin. Claws connate. Mandibles short, pincer-shaped. Abdomen with the 1st-4th visible sternites conglutinate together, 1st-6th tergites conglutinate together. Female genital segment (8th sternite) without an apophysis in general. Labial palpi inserted into cavities on the ventral surface of prementum, 2- or one-segmented or often palpi absent. Ovipositor not developed, styli always absent, coxites small or absent gonopore not opening between coxites. Lateral arms of metendosternite rounded and flat. Preoral cavity divided by a transverse bridge. Attelabinae

Subfamily Attelabinae Key to tribes.

 Head with temples very long, strongly constricted at the base. Elytra without scutellar striae. Posterior arms of tentorium originated from the gular suture, posterior tentorial pits far apart from the postocciput. Prementum with a pair of projections near the anterior margin. Labial palpi one-segmentedApoderini

1'.	Head with temples shorter, not constricted behind eyes. Each elytra with a scutellar stria. Posterior arms of tentorium ariser from gular and postoccipital sutures
2.	Eyes strongly approximated on frons. Anterior margin of prementum notched twice and sharply toothed thrice. Labial palp
2'.	absent Euopsin Eyes lateral, broadly separated. Anterior margin of prementum simple. Labial palpi two- or one-segmented
	Tribe Apoderini

	the base. Male rostrum rather long, without projection below the
	antennal insertion

Tribe Rhynchitini

Key to genera.

1.	Each elytron with a scutellar stria2
1'.	Elytra without scutellar striae4
2.	Rostrum rather short, straight. Head more or less constricted
	behind eyes
2'.	Rostrum slender, more or less curved. Head not constricted behind
	eyes3
3.	Tibiae indistinctly costate. Body slenderer
3'.	Tibiae distinctly costate on the dorsal margin, the costa finely
	serrate
4.	Rostrum very slender. Antennae slender, club loosely segmented,
	each segment of club much longer than wide. Male prothorax
	adorned with a spur on each side. Derm mottled with recumbent
	hairs and clothed further with long erect setae
4'.	Each segment of antennal club not longer than wide. Rostrum and
С	antennae less slenderer
5.	Male prothorax armed with a spur on each side. Terminal seg-
	ment of tarsi much longer than the 1st. Elytra with punctures not deeply striate
$\bar{5}'$.	Male prothorax unarmed. Terminal segment of tarsi at most
υ.	slightly longer than the 1st. Elytra punctured striate
	Involvulus Seidlitz

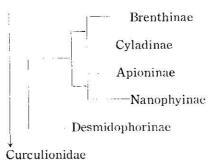

Family Brenthidae

In 1955 Crowson established a family Apionidae including Apioninae, Nanophyinae, Eurhynchinae (including *Cylas*) and Ithycerinae. Cyladinae may be separable from the Eurhynchinae by the position and number of the segment of labial palpi. As already be noted, Cyladinae has a close relation to Brenthidae auct. than to Apionidae auct. in the structures of labium and prothorax. Brenthidae auct. is very conspicuous in the straight and not or slightly clubbed antennae. The other characters studied are, however, similar to *Cylas* and *Apion*. From these points it may be better to combine the Brenthidae and Apionidae into a family.

Desmidophorus has been treated under the subtribe Ithyporina of the subfamily Cryptorrhynchinae basing on the sulcate prosternum and the general shape of body, but differs from the subfamily by the mandibles bearing a deciduous cusp, dentate tibiae on the external margin, developed and closely haired corbel of tibiae, Brenthid-Apionid-typed

aedeagus and proventriculus. From these point I would like to transfer the *Desmidophorus* from the Cryptorrhynchinae to Brenthidae of new sense tentatively until the larvae become clear.

The relationship of the subfamilies of Brenthidae could be illustrated as follows.

Key to subfamilies.

1.	Trochanters large, femora attached to their apex. Small species,
2014.0	not over 4.5 mm. Antennal club compact
1'.	Trochanters small, triangular. Larger species3
2.	Antennae not geniculate. Labial palpi one-segmented. Body pear-
	shaped, broadest at or behind the middle of elytra. Tarsal claws
	separatedApioninae
2'.	Antennae geniculate. Labial palpi 2-segmented. Body oval, broad-
	est at the shoulders. Tarsal claws connateNanophyinae
3.	Pygidium concealed, not striate. Visible segment of abdomen not
	entirely flat. Rostrum longer than wide4
3'.	Pygidium exposed, with a longitudinal median stria. Visible seg-
	ments of abdomen flat. Claws separated, bifide. Rostrum a little
	longer than wide, subquadrate in cross-section. Antennae straight.
	Front coxac contiguous. Labial palpi 3 segmented(Ithycerinae)
4.	Antennae geniculate. Front coxae separated. Prosternum before
	coxae deeply canaliculate. Mandible with a deciduous cusp, leav-
	ing a scar. Body oval, closely covered with scales. Labial palpi
	3-segmented
4'.	
14004	constricted near the posterior margin. Body slender, glossy. Labial
	palpi inserted into deep pits
5.	100 to 10
U.	Front coxae contiguous. Mesepimera concealed under elytra.
47	Claws connate at the base
5'.	Front coxae separated. Mesepimera exposed. Claws separated
	Brenthinae

Subfamily Brenthinae

Key to tribes.

	Key to tribes.
1.	Prothorax more or less compressed a little behind the anterior margin. Rostrum short, small, not sexually dimorphic
1'. 2. 2'.	Prothorax not compressed a little behind the anterior margin2 Inside of front tibiae strongly unidentate
3.	Smaller species, rarely over 10 mm in legth, femora unarmed in general
3'.	Larger species; femora dentate in general. Male antennae inserted into the middle of rostrum. Elytra dark-coloured with yellowish spots
	Tribe Calodromini
	Key to genera.
1.	Hind tibiae much shorter than tarsi, hind femora much exceeding posteriorly behind the apex of elytra; antennae inserted on the latero-ventral surface of rostrum
1'.	Hind legs normal; antennae inserted on the latero-dorsal surface of rostrum
2.	Underside of metarostrum semicircularly depressed
2'.	Underside of rostrum not depressed. Second interval of elytron not separated
	Tribe Stereodermini
	Key to genera.
1.	Antennae slender and long, often longer than body; head more or less sulcate; underside of rostrum with a row of small depressions on each side, inside of the depression velvety
1'.	Antennae shorter and robuster, not clubbed; front tibiae distinctly dentate
	Tribe Trachelizini
	Key to genera.
1. 1′.	Pronotum sulcate
2. 2'.	Each elytron with 2 costate intervals

Tribe Arrhenodini Key to genera.

1.	Male rostrum as broad as head, short, robust, female prorostrum cylindrical, straight
1'.	Male rostrum similar to that of female, much narrower than head, slender
	Subfamily Cyladinae
	Subfamily Apioninae
	Subfamily Nanophyinae
	Subfamily Desmidophorinae
	Desmidophorus Schönherr

Family Curculionidae

Curculionidae was divided into two major groups, Curculionidae adelognathi and Curculionidae phanerognathi by Lacordaire, 1863, Marshall, 1916, Reitter, 1916, etc. basing on the structures of mouth organs and the length of rostrum. Leconte and Horn, 1876, divided the Curculionidae into "Byrsopidae, Otiorrhynchidae and Curculionidae". In 1939 van Emden pointed out that Curculionidae could fundamentally be separable into two major groups on larval characters.

In the course of the present study I made an effort to find out the relationship of the subfamilies from the comparative morphology of adult. Following subfamilies could be said primitive from the structures of adult:

Sitoninae: Maxillary lacinia and galea separated, while the other subfamilies they are connate and forming mola. This subfamily may also be separable from the adelognathous Curculionidae by the short or vestigial ovipositor and normal mandibles.

Hyperinae: Hyperinae auct. and Notarinae auct. can not be separable by adult. Aedeagus of *Notaris* is of a Brenthid-type.

Ceuthorrhynchinae, Barinae, Magdalinae, some Cryptorrhynchinae: Abdominal spiracles on sclerites.

Mecyslobinae: Abdominal spiracles on sclerites, proventriculus less developed.

From the larval characters, *Rhynchaenus*, *Rhamphus*, *Mecinus* and *Orobitis* were classified into primitive groups by van Emden.

Cleoninae is greatly different from the other phanerognathous Curculionidae in the position and number of the segments of labial palpi and penis.

Carciliinae, Pissodinae, Styanacinae, Cryptorrhynchinae, Acicneminae, Magdalinae, Hylobiinae and Cossoninae are close to each other. Carcilinae has often been treated under Magdalinae, but the basis of elytra are not produced anteriorly, front coxae are separated and prosternum is canaliculate. Styanax was placed by Heller and Marshall in Hylobiinae, but the apices of tibiae are close to those of Pissodinae than to Hylobiinae. Protacalles and Protacallinus (both Cryptorrhynchinae), Seleucha (Hylobiinae) and Cotasteromimus (Pissodinae) are fairly close to each other. Cossoninae may be characterized by the inner setose fringe of tarsal groove of front tibia.

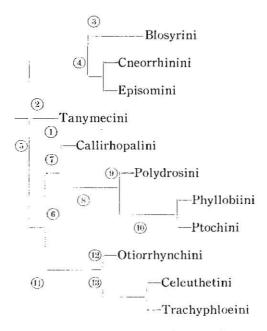

Posterior margins of 2nd—4th visible sternites of abdomen are curved posteriorly in the subfamilies Zygopinae, Ceuthorrhynchinae, Barinae, Tychiinae and Rhynchaeninae, this character corresponds with the articulating mechanism of sternites.

The general body form of Cioninae is often very close to some genera of Hyperinae such as *Phaenopholus*. Notarinae and Hyperinae have been treated as distinct subfamilies, but the long-nosed Hyperinae is very close to Notarinae auct. in various characters and I would like to combine these two subfamilies into a subfamily Hyperinae.

It may be better to separate the Rhynchaeninae from Tychiinae by the larval characters. Rhynchaenine larvae are pupate in the tunnel of leaf and the leaf miners of Tychiinae are pupate in the soil (Ochyromera, Elleschus, etc.)

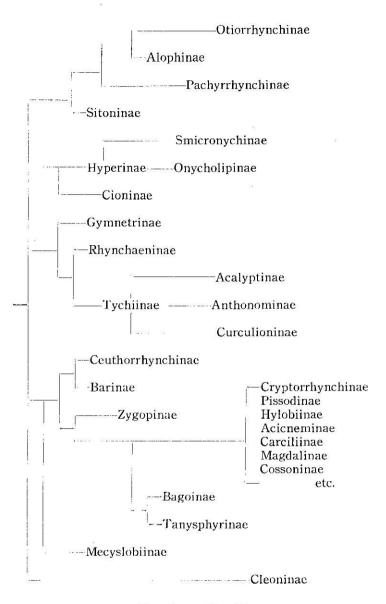

Subdivision of Curculionidae adelognathi into subfamilies can be said "artifitial" at present, because they are very often characterized by a single structure, for instance, Eremninae has been characterized only by the presence of the ocular lobes on prothorax, Cyphicerini of Eremininae is apparently a part of Ptochini from the point of comparative morphology and not close to Callirhopalini of the same subfamily. Brachyderinae and Otiorrhynchinae can be separable only by the position of the antennal scrobes. When the other characters are taken into consideration, Episomini of Otiorrhynchinae is apparently close to Cneorrhinini of Brachyderinae in the metendosternite, ovipositor and tibiae.

In this paper I would like to propose a new system of Curculionidae adelognathi from the structures of metendosternite, ovipositor and the other characters as follows:

- 1. Metendosternite Y-shaped or with lateral arms. Pronotum with vibrissae.
- 2. Metendosternite with lateral arms.
- 3. Ovipositor with coxite entirely subdivided. Hind tibiae with corbel open.
- 4. Ovipositor with coxite incised. Hind tibiae with corbel enclosed.
- 5. Metendosternite Y-shaped, without lateral arm.
- 6. Anterior margin of metendosternite inflected.
- Ovipositor with coxite incised. Prementum entirely covers the preoral cavity.
- Ovipositor developed, divided into two parts, basal part very often membraneous. Prementum not completely covers the preoral cavity.
- 9. Ovipositor with styli present.
- 10. Ovipositor with styli absent.
- 11. Anterior margin of metendosternite not inflected.
- 12. Ovipositor less developed, coxite simple or incised.
- 13. Ovipositor developed, basal major part membraneous, terminal sclerites subdivided into two parts by a longitudinal membrane.

The relationship of the subfamilies of Curculionidae could be illustrated as follows:

Key to subfamilies.

1.	Antennae with funicle 5-segmented.	Tibiae mucronate or unarmed.
		2
1'.	Antennae with funicle 6- or 7-seg	gmented3
0	Materians and Same between	the been

2. Metepimera exposed. From between eyes narrower than the base of rostrum. Posterior margins of 2-4 visible segments of abdomen

	curved posteriorly at the side. Pygidium concealedCioninae
2'.	Metepimera concealed. Frons between eyes as broad as or broader
	than the base of rostrum. Posterior margins of 2-4 visible
	segments of abdomen straight. Pygidium exposedGymnetrinae
3.	Tarsi 3-segmented, 4th, 5th segments and claws absent. Posterior
	margins of 2-4 visible segments of abdomen curved posteriorly
	at the sides. Procoxae contiguous. Metepimera concealed. Each
	tibia armed with an uncus
3'.	Tarsi 5-segmented; 4th segment small and often invisible4
4.	Mesepimera strongly ascended upwards between the base of pro-
1.	notum and elytra, therefore they are visible from above. Hind
	tibiae unarmed or each with a mucro. Front coxae separated.
	Posterior margins of 2-4 visible segments of abdomen curved
.,	posteriorly at the sides. Eyes lateral5
<i>4'</i> .	Mesepimera not ascended; or if ascended, tibiae each armed with
olee-	an uncus and eyes strongly approximated dorsally6
5.	Metasternum contiguous with the 1st segment of abdomen between
	hind coxae and metepisterna. Metepisterna parallel-sided. Tibiac
	unarmed or each with a small mucro. Corbel of tibiae opened.
	Claws often appendiculate. Pronotum with ocular lobes. Small,
	oval and convex species
5'.	Metasternum separated from 1st segment of abdomen on each
	side, hind coxae contiguous with metepisterna. Metepisterna
	widened from the middle towards the posterior ends. Tibiae mu-
	cronate, corbel with the inner bare carina developed. Claws simple.
	Body oval, elongate or parallel-sidedBarinae
6.	Hind femora much thicker than the anteriors. Hind tibia with
	the corbel lying entirely on the dorsal edge, unarmed. Mesepimera
	not ascended upwards. Eyes large, strongly prominent or confluent
	on frons. Posterior margins of 2-4 visible segments of abdomen
	curved posteriorly at the sides. Claws separated, appendiculate
6'.	Hind femora not thicker than the anteriors, corbels of tibiae
	oblique, tibiae truncate or armed at the apex7
7.	Eyes large, flat, closely approximated to each other on frons,
	occupying the major part of frons. Posterior margins of 2-4
	visible segments of abdomen curved posteriorly at the sides. Tibiae
	uncinate. Metepimera often ascended upwardsZygopinae
7'.	Eyes not closely approximated on frons; if approximated, metepi-
5.5	mera not ascending upwards or posterior margins of abdominal
8.	segments straight
o.	Mandibular motion vertical. Rostrum very slender. Claws appen-
	diculate, posterior margin of 2nd visible segment of abdomen curved
	nosteriorly at the sides. Eyes not prominent from the outline of

	headCurculioninae
8'.	Mandibular motion horizontal9
9.	Posterior margins of 2-4 visible segments of abdomen curved
	posteriorly at the sides. Front coxae contiguous. Claws separated,
	appendiculate. Rostrum rather robust, nearly as long as head and
	pronotum taken together. Antennae inserted before the middle of
	rostrum. Rostrum perpendicular to the axis of body in repose.
	Smaller speciesTychiinae
9'.	Posterior margins of 2-4 visible segments of abdomen straight;
	if curved, front coxae separated or claws simple
10.	Tibiae mucronate or unarmed, the outer setose fringe of corbel
	forming a transverse apical border to the tibia, though it is often
	continued round the external angle and along the dorsal edge,
	forming a strong curve, which is usually subrectangular11
10'.	Tibiae uncinate, inner carina of corbel developed, uncus arisen
	from this carina. The outer setose fringe of corbel oblique and
4	straight or gently curved, or the fringe vestigial20
11.	Mandibles with a deciduous cusp, leaving a scar. Rostrum short.
	Prementum not pedunculateOtiorrhynchinae
11'.	Mandibles without scar
12.	Mesepimera very narrow. Elytra contiguous with mesepisterna.
	Procoxae separated. Rostrum very short. Claws simple, free.
	Corbels opened. Postmentum not pedunculate Pachyrrhynchinae
12'.	Elytra separated from mesepisterna. Procoxae contiguous, or if
	separated rostrum slender
13.	Exterior surface of mandibles with scales and hairs. Rostrum
	short, broader than long. Postmentum not pedunculate. Ovipositor
	less developed or vestigial. Maxillae with lacinia distinct
	Sitoninae
13'.	Exterior surface of mandibles at most with several hairs. Rostrum
	longer than wide. Postmentum pedunculate14
14.	Procoxae separated. Rostrum slender. Anterior margins of pro-
	sternum nearly straight. Front coxae lying on the posterior 1/3
	of prosternum. Metepimera concealed
14'.	Procoxae contiguous, lying about the middle of prosternum16
15.	Eyes convex. Lateral margins of pronotum costate. Claws simple
	Petalochilinae
15'.	Eyes flat. Lateral margins of pronotum not costate. Claws ap-
	pendiculate. Pygidium exposedAcalyptinae
16.	Median and hind tarsi not spongy beneath, 3rd segment of front
	tarsi with long hairs beneath. Front claws much thicker than
	the posteriors. Median and hind corbels semienclosed. Outer
	apical edge of front tibiae strongly protruded. Rostrum robust,
	shorter than pronotum, dorsal surface nearly flat. Antennae in-

	serted near the apex of rostrum, 6-segmented. Ventral longitudinal
	flange of metendosternite connate with a median longitudinal line
	of metasternum in entire lengthOnycholipinae
16'.	All tarsi spongy beneath. All claws similar to each other. Outer
	apical edge of front tibiae simply rounded. Metendosternite
	normal
17.	Outer surface of mandible strongly compressed and blade-like
	towards the apex, inner surface deeply excavated. Rostrum robust,
	subquadrate in cross-section. Antennae inserted near the apex of
	rostrumAlophinae
17'.	Outer surface of mandible not compressed, inner surface with 2
	or 3 teeth, not excavated18
18.	Eyes lateral. Prosternum not canaliculated. Claws free19
18 ′ .	Eyes closely approximated beneath to each other. Prosternum with
	a shallow canal before coxae. Claws connate. Rostrum separated
	from head by a transverse depression. Posterior margins of 2-4
	visible segments of abdomen curved posteriorly at the sides
19.	Eyes strongly convex, distinctly prominent from the outline of
	head. Rostrum cylindrical. Front coxae lying at the middle or
	a little before the middle of prosternum. Claws often appendicu-
	lateAnthonominae
19'.	Eyes not prominent from the outline of head. Front coxae lying
	on the middle or behind the middle of prosternum. Claws simple.
	Antennae inserted near the apex of rostrumHyperinae
20.	Front coxae separated, with a few exceptions ¹⁾ 21
20'.	Front coxae contiguous
21.	Claws bifid, inner branches connate to each other. Basis of elytra
	strongly produced anteriorly, covering the basal part of pronotum.
	Hind angles of pronotum angulate. Front femora much thicker
	and a little longer than the posteriorsMecyslobinae
21'.	Claws separated. Basis of elytra not laminate in general, basal
	part of pronotum entirely exposed 22
22.	Prosternum canaliculate23
22'.	Prosternum flat or depressed25
23.	Claws simple. Ocular lobes of pronotum developed. Eyes partly
	covered by ocular lobes in repose
23'.	Claws appendiculate, ocular lobes of prothorax absent. Eyes
	separated from prothorax in repose

¹⁷ Some genera of the Ithyporini are close to a certain genus of Lithinini in having the connate front coxae and canaliculate prosternum before coxae, but the formers may be separable from the latter by the slenderer rostrum and antennae which are inserted far behind the apex of rostrum.

24.	Rostrum very short, broader than long, subquadrate in cross-section Antennae short, scape nearly as long as the first two segments o
	funicle taken together
24'.	Rostrum slender, cylindrical. Antennae slenderer, scape nearly as
21.	long as all the segments of funicle taken together
25	Cryptorrhynchinae
25.	Tarsal grooves of front tibiae rounded posteriorly and fringed with
	setae on the lower part of the margins a little above the lower
	edge of tibia. Third tarsal segments broader than the 2nd, bilobed
25'.	Front tibiae fringed with setae on the lower edge near the apex
	tarsal grooves of front tibiae opened behind. Tarsi with the 3rd
	segment not or a little broader than the 2nd. Femora unarmed
	Body slender, parallel-sidedCossoninae
26.	Antennal scrobes oblique, the posterior ends closely approximated
	or confluent under the base of rostrum. Ocular lobes of pronotum
	developed. Rostrum longer than pronotum, antennae inserted be-
	hind the middle. Abdominal process between hind coxae very
	broad, broader than coxa
26'.	Antennal scrobes separated throughout. Ocular lobes of pronotum
	very weak or absent. Antennae inserted into the middle—apical
	1/3 of rostrum
27.	Labial palpi one-segmented or absent. Claws connate28
27'.	Labial palpi 3-segmented. Claws usually separated
28.	Labial palpi one-segmented, globular, inserted into a hole at the
	ventro-lateral edge a little before the middle of prementum. Pre-
	mentum between palpi transversely depressed. Metepimera ex-
	posed. Fifth tarsal segment longer than the 3rdCleoninae
28'.	Labial palpi absent. Prementum not divided by a depression.
20.	Metepimera concealed. Rostrum robust, as broad as or broader
	than long, female rostrum swollen. Fifth tarsal segment not longer
	than the 3rd
29.	Basis of elytra laminate, strongly produced anteriorly and covering
40.	the basal part of pronotum
29′.	
49.	Basis of elytra not produced anteriorly, basal margin of pronotum
20	entirely exposed
30.	Metepimera concealed, hind angles of pronotum simply rounded.
	Fifth tarsal segment armed with a pair of laminate projections
oot	behind claws. Body rhombicTrigonocollinae
30′.	Metepimera exposed. Hind angles of pronotum angulate, produced
	latero-posteriorly. Fifth tarsal segment simple. Body parallel-sided
31.	Fifth tarsal segment longer than the 3rd. Anterior margin of
	prosternum excavated. Ocular lobes often present32

31.′ 32. 32′.	Fifth tarsal segment not longer than the 3rd, anterior margin of prosternum not excavated. Ocular lobes absent. Subaquatic species
	Subfamily Cioninae
	Key to genera.
1. 1'.	Tarsus with a single claw
2.	Front coxae separated. Prosternum before coxae deeply canalicu-
o.l	lated
2'.	Front coxae contiguous. Prosternum flat or depressed
3.	Male tibia mucronate. Elytra without a sutural spot. Anterior margin of prosternum straight or slightly sinuate. Claws of the same length in both sexes
3′.	Tibiae unarmed in both sexes. Elytra with a sutural spot. Anterior margin of prosternum excavated. Claws of the same length in female, the inner claw shorter than the outer one in male
	Subfamily Gymnetrinae
	Key to genera.
1.	Front coxae contiguous. Claws connate. Rostrum shorter
1′.	Front coxae separated. Claws free. Rostrum longer
	Subfamily Anoplinae
Uni	que genus
	Subfamily Rhynchaeninae
	Key to tribes.
1.	Eyes confluent on frons. Rostrum perpendicular to the axis of
1'.	body or received upon breast in repose
	Dinorrhopalini

Tribe Rhynchaenini

Key to genera.

	Key to genera.
1.	Tibiae unarmed at tip, hind tibiae flattened dorsally in entire
	length. Rostrum perpendicular to the axis of body in repose
1'.	Anterior four tibiae armed with uncus. Rostrum received on
	breast in general2
2.	Antennae straight, inserted between eyesRhamphus Clairville
2'.	Antennae geniculate, inserted into rostrum
	,
	Tribe Dinorrhopalini
	Key to genera.
1.	Rostrum very short, broader than long. Antennae inserted between
	eyes. Front coxae separated. Inner apical edge of hind tibia
	pointed
1'.	Rostrum as long as or longer than wide. Antennae inserted into
	rostrum. Front coxae contiguous. Inner apical edge of hind tibia
	rounded
	Subfamily Ceuthorrhynchinae
	Key to tribes.
1.	First visible segment of abdomen narrower than the 2nd, subdivided
	into three parts by coxal cavities. Rostrum tapered towards the
	apex. Body globular. Claws bifid, inner branches entirely con-
	tiguous to each otherOrobitini
1'.	First visible segment of abdomen broader than the 2nd, not sub-
	divided. Rostrum parallel-sided2
2.	Hind femora clavate, much thicker than the anteriors. Rostrum
	a little shorter than pronotum. Claws simple. Eyes partly con-
	cealed under pronotum in repose
2'.	Hind femora not or slightly thicker than the anteriors, or rostrum
	longer than pronotum if hind femora clavate. Claws often ap-
	pendiculate3
3.	Elytra with the 8th intervals not broader than the others at the
	base, humeral tubercles absent, subapical swellings absent. Each
	interval armed with a row of tubercles. Pronotum without lateral
	tuberclesScleropterini
3'.	Elytra with the 8th intervals convex, much broader than the others
	at the base4
7	D / D / D / D / D / D / D / D / D / D /

4'. Rostrum slender, longer than pronotum. Ocular lobes developed
covering the major parts of eyes in repose
5. Scutellar lobe of pronotum costate, sharply pointed and strongly
produced posteriorly, covering scutellum. Hind femora thicker than the anteriors
5'. Scutellum exposed. Posterior margin of pronotum weakly bisinuate
Hind femora not or a little thicker than the anteriors
Cutioningheim

Unique genus Hypurus Rye
Tribe Scleropterini
Unique genus
Tribe Rhinoncini
Key to genera.
1. Antennal funicle 6-segmented. Prosternum Letween coxae narrow
not canaliculate before coxae
1'. Antennal funicle 7-segmented. Prosternum between coxae broader,
canaliculate before coxes2
2. Femora each armed with a small toothRhinoncomimus Wagner
2'. Femora unarmed
Tribe Mecysmoderini
Unique genus
(D. 11 O. 11
Tribe Ceuthorrhynchini
Key to genera.
1. Antennal funicle 7-segmented
1'. Antennal scape adorned with a very long spine at the apex.
Pectoral canal extending into metasternum. Pronotum with a pair of large tubercles at the middle
2'. Antennal scape rounded or pointed at the apex4
3. Tibiae flattened, toothed or angulate on the outer side. Pronotum
not depressed before scutellum
3'. Tibiae neither flattened nor toothed. Pronotum deeply depressed
before scutellum
4. Intervals of elytra each with a row of pointed tubercles or setiger-
ous granules. Pronotum with a pair of tubercles, basal margin
nearly straight5

4'.	Dorsal part of elytra neither tuberculate nor granulate7
5.	Elytra with a white scutellar spot
5'.	
0.	Elytra without a scutellar spot. Black. Each interval of elytra
	with a row of pointed tubercles and a row of dark setae. Pronotum
	convex, glossy. Mesosternum excavatedZacladus Reitter
6.	Black. Pronotum strongly punctured. Tibiae simple, femora
	nemad
at	armed
6'.	Antennae, rostrum and legs reddish. Pronotum weakly punctured.
	Median tibiae with a small hair tuft before the apex. Each interval
	of elytra clothed with a row of crect white scales. Mesosternum
	weakly depressed
7.	
	Pectoral canal extending onto metasternum8
7'.	Pectoral canal not extending behind front coxae
8.	Tibiae flattened, not dilated towards the apex. Corbels of hind
	tibiae ascended anteriorly. Body entirely or partly red
01	
8'.	Tibiae not flattened, dilated towards the apex. Corbels not
	ascended. Body black
9.	Intervals of elytra each armed with a row of pointed setigerous
	granules. Pectoral canal extending onto metasternum
	Ceuthorrhynchidius J. du Val
O.	Intervals of clytra unarmed. Pectoral canal not extending behind

Rostrum not separated from frons. Prosternum deeply depressed before coxae. Pronotum with ocular lobes. Pygidium exposed. Body rhombic . Centrinopsis Roelofs Elytron provided with 10 punctured striae, 9th and 10th striae separated throughout
1. 1'. 2.	Subfamily Barinae Key to genera. Elytron provided with 8 punctured striae, lateral 3 striae not reaching the base, 7th and 8th striae confluent above the 2nd segment of abdomen. Rostrum not separated from frons. Prosternum deeply depressed before coxae. Pronotum with ocular lobes. Pygidium exposed. Body rhombic Centrinopsis Roelofs Elytron provided with 10 punctured striae, 9th and 10th striae separated throughout 2. Tarsi each with a single claw. Rostrum not separated from frons. Pectoral canal extending to the middle of front coxae. Antennae with funicle widened terminally, continuous to club. Pygidium exposed. Posterior margin of 5th visible segment of male abdomen quadrately projected posteriorly at the middle, the projection glossy. Body rhomic Barinomorphus Morimoto
1. 1'. 2.	Subfamily Barinae Key to genera. Elytron provided with 8 punctured striae, lateral 3 striae not reaching the base, 7th and 8th striae confluent above the 2nd segment of abdomen. Rostrum not separated from frons. Prosternum deeply depressed before coxae. Pronotum with ocular lobes. Pygidium exposed. Body rhombic Centrinopsis Roelofs Elytron provided with 10 punctured striae, 9th and 10th striae separated throughout 2 Tarsi each with a single claw. Rostrum not separated from frons. Pectoral canal extending to the middle of front coxae. Antennae with funicle widened terminally, continuous to club. Pygidium exposed. Posterior margin of 5th visible segment of male abdomen quadrately projected posteriorly at the middle, the projection glossy. Body rhomic Barinomorphus Morimoto Tarsi each with a normal, paired claws 3
1. 1'. 2.	Subfamily Barinae Key to genera. Elytron provided with 8 punctured striae, lateral 3 striae not reaching the base, 7th and 8th striae confluent above the 2nd segment of abdomen. Rostrum not separated from frons. Prosternum deeply depressed before coxae. Pronotum with ocular lobes. Pygidium exposed. Body rhombic Centrinopsis Roelofs Elytron provided with 10 punctured striae, 9th and 10th striae separated throughout 2 Tarsi each with a single claw. Rostrum not separated from frons. Pectoral canal extending to the middle of front coxae. Antennae with funicle widened terminally, continuous to club. Pygidium exposed. Posterior margin of 5th visible segment of male abdomen quadrately projected posteriorly at the middle, the projection glossy. Body rhomic Barinomorphus Morimoto Tarsi each with a normal, paired claws 3 Hind femora exceeding the apex of elytra, hind tibiae very short,
1. 1'. 2.	Subfamily Barinae Key to genera. Elytron provided with 8 punctured striae, lateral 3 striae not reaching the base, 7th and 8th striae confluent above the 2nd segment of abdomen. Rostrum not separated from frons. Prosternum deeply depressed before coxae. Pronotum with ocular lobes. Pygidium exposed. Body rhombic Centrinopsis Roelofs Elytron provided with 10 punctured striae, 9th and 10th striae separated throughout 2 Tarsi each with a single claw. Rostrum not separated from frons. Pectoral canal extending to the middle of front coxae. Antennae with funicle widened terminally, continuous to club. Pygidium exposed. Posterior margin of 5th visible segment of male abdomen quadrately projected posteriorly at the middle, the projection glossy. Body rhomic Barinomorphus Morimoto Tarsi each with a normal, paired claws 3

	not separated from frons. Body cylindrical, linear. Elytra each with a fovea near the apex in male, subapical swellings absent
3'.	Hind femora not exceeding the apex of elytra, hind tibiae nearly
٥.	as long as femora. Elytra without fovea4
,	
4.	Rostrum not separated from frons, shorter than pronotum. Pygi-
	dium oblique or horizontal, entirely concealed at least in female.
702	Body elongate, parallel-sided
4'.	Rostrum separated from frons by a transverse depression, often
	the depression weak5
5.	Prosternum deeply canaliculate, inside of the canal glossy. Body
	rhombic6
5'.	Prosternum not or shallowly canaliculate, inside of the canal not
	glossy, the canal not reaching front coxae7
6.	Pygidium exposed in both sexes. Posterior margin of the 5th
٠.	visible segment of male abdomen quadrately projected posteriorly
	at the middle, the projection glossy. Claws connate
	Barinomorphoides Morimoto
6'.	
0.	Pygidium entirely concealed in both sexes. Claws free. Corbel
	with the inner canina strongly laminate, dorsal end of the carina
	angulate
7.	Tibiae uncinate and further mucronate, the mucro rectangular to
	the axis of tibia, inner margin of tibiae serrate. Pronotum
	broadest at the base. Claws connate. Labial palpi one-segmented
7'.	Tibiae uncinate, inner margin not serrate. Palpi 3-segmented 8
8.	Pygidium concealed. Mesosternum lying on the same level with
	pro- and metasternum. Scutellum invisibleKeibaris Chûjô
8'.	Pygidium exposed. Mesosternum oblique or depressed. Scutellum
	visible
	Subfamily Zygopinae
	(A)
	Key to tribes.
1.	Prosternum canaliculate, each side of the canal keeled
1'.	Prosternum flat or depressed4
2.	Scutellar lobe of pronotum developed and covering scutellum
027	Lobotrachelini
2'.	Base of pronotum straight, arched or bisinuate3
3.	Anterior tibiae more or less depressed, with a fine stria along the
	lateral margin, which is bordered with fine carinae. Mesepimera
	strongly ascended upwards between the base of pronotum and elytra,
	therefore they are clearly visible from above. Small species
	Isorrhynchini

3'. 4. 4'. 5.	Anterior tibiae not or rarely depressed, simple or with a lateral keel. Mesepimera not ascended upwards. Metepisterna parallel-sided
5′.	parallel-sided, posterior coxae broadly separated from lateral margin of elytra
	Tribe Lobotrachelini
	Key to genera.
1.	Pectoral canal confined to prosternum, open behind, mesosternum slightly depressed or flat, not groovedLobotrachelus Schönherr
1'.	Pectoral canal prolonged to mesosternum, sharply limited behind. Procoxae comparatively larger and legs shorterMetetra Pascoe
	Tribe Othippiini
	Tribe Mecopini
	Key to genera.
1.	Antennae with club very long, cylindrical, first segment of club as long as all the segments of funicle taken together
1'. 2.	Neomecopus Hustache Antennae with club normal, oval or fusiform
2'.	Femora with the tooth small and normal, posteriore tibiae parallel-sided. Anterior coxae not contiguous. Prosternum with a pair of long spines in male

Tribe Isorrhynchini

Key to genera.

Scutellum depressed, oblique to the axis of body, posterior margin much lower than the level of elytra. Pronotum with weak ocular lobes. Front femur a little thicker and the tooth larger than the hind ones. Each femur with a pair of setae between the tooth and apex. First segment of abdomen as long as the 2nd and 3rd taken together. Lateral tubercles on pronotum absent. Both sides of prosternal canal sharply keeled and the canal reaching Scutellum normal, flat or slightly covex. Ocular lobes on pronotum absent2 Front femora much thicker than posterior ones and with a very large tooth, with a pair of long setae between the tooth and apex. Front tibiae with several long erect or suberect setae on the inner margin near the base. Prosternal canal limited by the front coxae, both sides of the canal bordered with obtuse and broader keels. Pronotum with lateral tubercles... Telephae Pascoe Front femora scarcely thicker than posterior ones, the tooth not veryl arge. Front femora and tibiae without special setae.......3 Prosternal canal reaching the posterior margin of front coxae, 3. both sides of the canal sharply limited by keels. First segment of abdomen as long as the 2nd and 3rd taken together. Lateral Prosternal canal reaching the anterior margin of middle of front Prosternal canal bordered with obtuse and broad keels, the keel reaching the anterior margin of front coxa. First segment of abdomen as long as the 2nd at the lateral margin. Lateral tuber-4'. Prosternal canal reaching the middle of front coxae and bordered with sharp keels. First segment of abdomen as long as the 2nd
