**Abstract.** A gall midge species forming leaf margin roll galls on *Robinia pseudoacacia* L. (Fabaceae) was newly found in Japan and South Korea. Based on morphological features, this gall midge was identified as *Obolodiplosis robiniae* (Haldemann), which is native to eastern North America. There was no sequential variation among five individuals from Japan and South Korea. Since *R. pseudoacacia* is an alien plant, this gall midge is likely to have entered Japan and South Korea from North America.

**Key Words:** gall midge, leaf margin roll gall, new distribution record, *Robinia pseudoacacia*, alien plant, Nearctic species.

### Introduction

In July 2002, one of us, FK, found gall midge larvae forming leaf margin roll galls

---

\* Contribution from the Entomological Laboratory, Faculty of Agriculture, Kyushu University, Fukuoka (Ser. 5, No. 96).

on *Robinia pseudoacacia* L. (Fabaceae) in Fukuoka Prefecture, Japan. Almost simultaneously, a similar gall was also found in the suburbs of Seoul, South Korea by one of us, HL. The shape of these galls is very similar to each other, suggesting a possibility that the gall midges from both countries are identical. In this study, we identify the gall midge species from Japan and South Korea on the basis of morphology. We also compare sequences of partial mtDNA COI region between the Japanese and South Korean individuals to detect intra-specific variations at the DNA level, if they are identical.

*Robinia pseudoacacia* is a North American species and not native to eastern Asia (Satake *et al.*, 1989), and no midge galls have been found so far on *R. pseudoacacia* in Japan and South Korea. As has been noted in Yukawa & Uechi (1999), most of galling insects cannot expand their host range to alien species. Therefore, a question arises as to reasons why such a leaf margin roll gall was found on an alien plant. A possible explanation is discussed for this phenomenon based on information (Yukawa & Masuda, 1996) including collection and distribution records of midge galls on fabaceous plants in Japan.

## Materials and Methods

### *Collection, preservation, and identification*

The larvae and pupae of the gall midge were collected by FK in July 2002 from *R. pseudoacacia* growing in the Kyushu University Forest, Sasaguri Town, Fukuoka Prefecture, Japan. Some of them were preserved in 75% ethanol for morphological study or in 99.5% acetone for DNA analysis. Remaining pupae and larvae were kept in a plastic bag to rear adults. The adults emerged from July 17 to 20.

In South Korea, larvae of the gall midge were collected by HL on August 9, 2002 from Seodundong, Suwon, South Korea and kept in a plastic cage to rear adults. The adults emerged from August 11 to 13. Some of the adult specimens were sent to JY for identification. In addition to Suwon, this gall midge was observed in Anyang and Seoul from June to August 2002. Adult emergences were also observed on July 11-12 from the galls collected in Chungju and through May 27 to June 7 from the galls collected in Daejeon.

The generic position of these gall midges was determined using keys to genera of Cecidomyiidae (Gagné, 1981). The species identification was confirmed through the courtesy of Dr. R. J. Gagné by comparing the Japanese and South Korean specimens with those kept in the U.S. National Museum, Washington, D.C., USA.

The specimens that were used in this study are kept in the collection of Entomological Laboratory, Faculty of Agriculture, Kyushu University and that of Laboratory of Insect Systematics, College of Agriculture and Life Science, Seoul National University, South

Korea. Some specimens are also kept in the U.S. National Museum, Washington, D.C., USA.

### **DNA analysis**

For DNA analysis, three individuals of Japanese (collected on July 15, 2002) and two individuals of South Korean specimens (collected on August 9, 2002) were used. For every individual, total DNA was extracted from the whole body with the DNeasy tissue kit (Qiagen, Japan), following the manufacturer's instructions. A region of the cytochrome oxidase subunit I (COI) gene of mtDNA was amplified by polymerase chain reaction (PCR) (Saiki *et al.*, 1988). This region has been effectively used for the analysis for intra- or inter-specific variations in various genera of Cecidomyiidae (Shirota *et al.*, 1999; Yukawa *et al.*, 2003; Uechi *et al.*, submitted to *Bull. Ent. Res.*). The primers used for the amplification were as follows: forward; 5'-GGATCACCTGATATAGCATTC-3' (COIS) and reverse; 5'-CCCGGTAAAATTAAAATA-TAACTTC-3' (COIA) (Funk *et al.*, 1995). The amplified products were purified with QiAquick PCR purification kits (Qiagen, Japan) following the manufacturer's instructions. The purified products were sequenced by the dideoxynucleotide cycle sequencing procedure with the Dye-Terminator cycle sequencing procedure with the Dye-Terminator cycle sequencing kit (Perkin-Elmer, Warrington, UK) and TGRADIENT thermal cycler (Biometrika). Sequencing electrophoresis was done on an 11% Long Ranger™ gel with a LIC-4200S-2 automated DNA sequencer (Aloka Co. Ltd, USA). Both strands on the PCR products were sequenced.

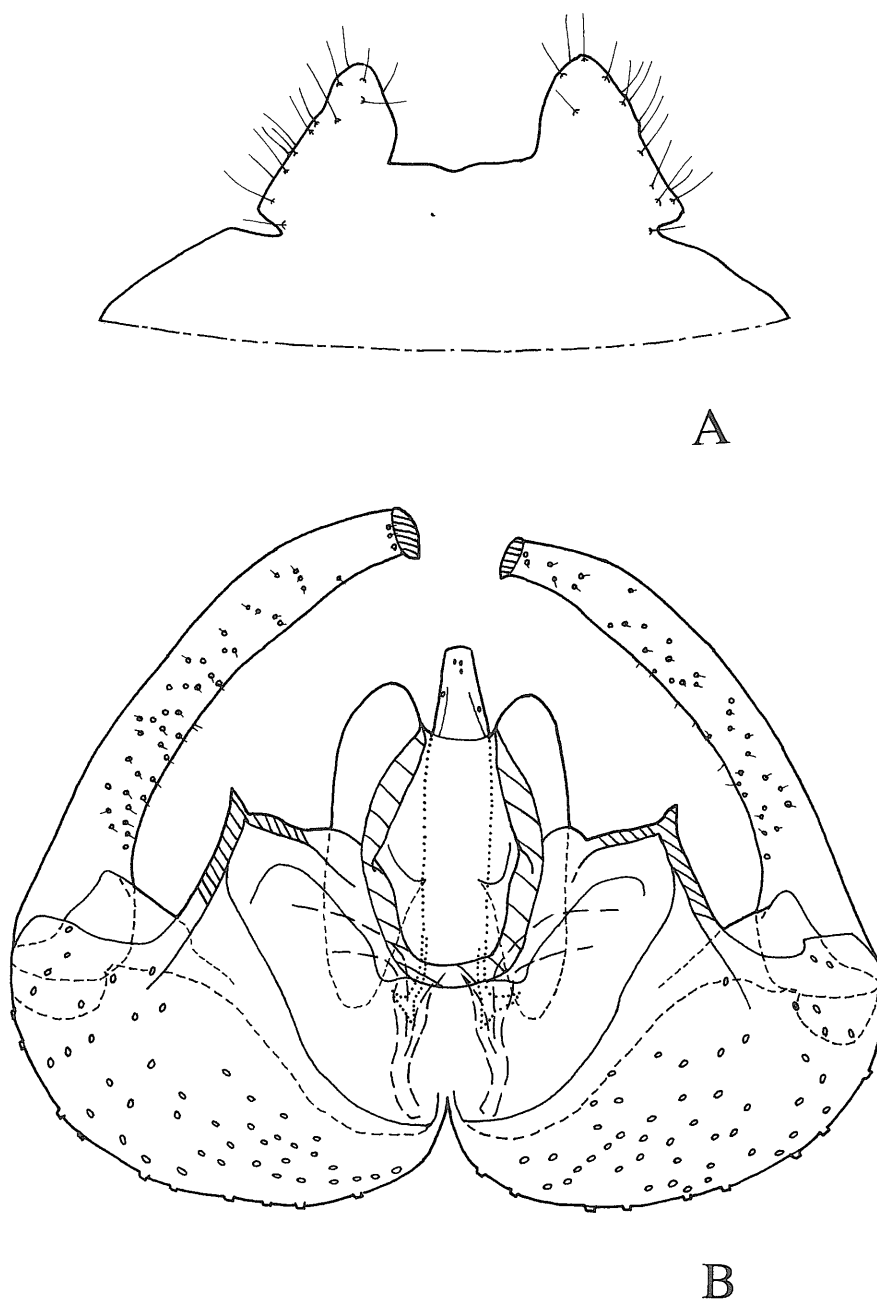

The nucleotide sequence data reported in this paper will appear in the DNA Data Bank of Japan, European Molecular Biology Laboratory, and GenBank nucleotide sequence databases with the following accession numbers: AB106524- AB106528.

## **Results and Discussion**

### **Identification**

We confirmed that the gall midge species from Japan and South Korea have the following common characteristics: post vertical peak absent; palpus four-segmented; antenna with 12 flagellomeres; last flagellomere not tiny; tarsal claw simple, approximately as long as empodium on all legs; basal section of Rs strong; Rs joining C posterior to wing apex. Male genitalia (Fig. 1): cerci large, nearly divided; hypoproct modified into two orbicular lobes surrounding aedeagus; gonostylus setulose, long and narrow, longer than gonocoxite; mediobasal lobe not present.

Based on these characteristics, we concluded that the gall midges from Japan and South Korea are identical and belong to the genus *Obolodiplosis* Felt, 1908, which has

**Fig. 1.** *Obolodiplosis robiniae* (Haldemann). A: dorsal view of hypandrium and cerci;  
B: dorsal view of male genitalia, hypandrium and cerci are removed.

only one species, *Obolodiplosis robiniae* (Haldemann, 1847), in the world. We identified the Japanese and Korean species as *O. robiniae* and Raymond J. Gagné (2002, personal communication) confirmed our identification.

### **DNA analysis**

The amplified mtCOI gene fragment was 439 bp long. This region corresponded to the bases 1752-2190 of the genome of *Drosophila yakuba* Burla (Diptera: Drosophilidae) (Clary & Wolstenholme, 1985). There was no sequential variation among five individuals from Japan and South Korea (see the accession numbers indicated in the Materials and Methods). These results of DNA analysis supported the morphological confirmation that the Japanese and South Korean gall midges were identical.

### **Accidental introduction**

In Japan, 16 sorts of insect galls are known to occur on fabaceous plants and 10 of them are midge galls (Yukawa & Masuda, 1996). However, none of the midge galls are produced on *R. pseudoacacia*, although *Aphis craccivora pseudoacaciae* Takahashi (Aphididae) makes leaf roll galls on that plant (Yukawa & Masuda, 1996). As shown in Gagné (1989), *Obolodiplosis* is a Nearctic genus and no gall midges of *Obolodiplosis* were previously recorded from eastern Asia. In addition, the only known host plant of *O. robiniae* is *R. pseudoacacia*, which is native to North America (Satake *et al.*, 1989) and has been introduced first in 1877 to Japan from North America (Makino, 1940).

These evidences suggest that this gall midge is likely to have entered Japan from North America rather than expanded its host range to *R. pseudoacacia* from some other fabaceous plants native to eastern Asia.

The time of arrival is hardly determined, but there are a few evidences supporting its relatively recent arrival. There were no collection records of this gall midge until today in Japan, even though one of us, JY, and his colleagues have searched for galling arthropods on many occasions over a period of more than 30 years (Yukawa & Masuda, 1996). In addition, this gall midge has never broken out in Japan and South Korea on *R. pseudoacacia* that is now widely planted in both countries, in spite of the fact that herbivores frequently increase their population density tremendously soon or some time after arrival at new habitats (e.g., Elton, 1958; Miyashita, 1977; Yukawa, 1984).

### **Acknowledgements**

We would like to express our thanks to Dr. R. J. Gagné (Systematic Entomology Laboratory, PSI, Agricultural Research Service, USDA) for confirming our identification. Our thanks are also due to Dr. O. Tadauchi, Dr. S. Kamitani, Messrs. D. Yamaguchi,

M. Tokuda, and S. Sato (Entomological Laboratory, Kyushu University) for their support and help.
