Abstract : This paper analyses a recurrent behavior of dynamic fuzzy systems defined by fuzzy relations on a metric space. We show the existence of cyclic classes of the dynamic fuzzy system and give an ergodic theorem for the fuzzy transition.

Keyword : Cyclic class; ergodic theorem; dynamic fuzzy system; recurrence; fuzzy relation.

1. Introduction and notations

Limit theorems of a sequence of fuzzy sets defined successively by fuzzy relations are first studied by Bellman and Zadeh [1]. Kurano et al. [3], under a contraction condition, studied the limiting behavior of fuzzy states defined by the dynamic fuzzy system with a compact space. A notion of recurrent sets for the dynamic fuzzy system is given by Yoshida [7]. This paper analyses the cyclic behavior of the dynamic fuzzy system.

In Section 2, we show the existence of cyclic classes, which are nested with respect to levels, for recurrent sets in the dynamic fuzzy system, using the methods of Chung [2]. In Section 3, we show a correspondence between a period of the cyclic classes and a limiting possibility of the fuzzy transition. By the use of the result, we give an ergodic theorem which is different from the ergodicity in the classical Markov chains. In the dynamic fuzzy system, the limit of the fuzzy transition equals to one of a finite/countable number of levels, and the states are classified into cyclic classes nested with respect to the levels. In Section 4, a numerical example is given to illustrate our idea.

2. Cyclic classes for dynamic fuzzy systems

Let a state space E be a complete metric space. Let a time space by $\mathbf{N} := \{0, 1, 2, \cdots\}$. Let $\tilde{q}$ be an upper semi-continuous fuzzy relation on $E \times E$ satisfying the following normality condition :

$$\sup_{x \in E} \tilde{q}(x, y) = 1 \ (y \in E) \quad \text{and} \quad \sup_{y \in E} \tilde{q}(x, y) = 1 \ (x \in E).$$

We denote a fuzzy set on E by its membership function $\tilde{s} : E \mapsto [0, 1]$ ([3]). Kurano et al. [3], under a contractive condition, studied the limiting behavior of a sequence of fuzzy

1

states $\{\tilde{s}_n\}_{n=0}^{\infty}$ given as follows : An initial fuzzy state $\tilde{s}_0$ is a given fuzzy set on E, and we define

$$\tilde{s}_{n+1}(y) := \sup_{x \in E}\{\tilde{s}_n(x) \wedge \tilde{q}(x,y)\}, \quad y \in E, \ n = 0,1,2,\cdots. \tag{2.1}$$

This is called a dynamic fuzzy system (see [3, 6, 8, 9]). We define a sequence of fuzzy relations, $\{\tilde{q}^n\}_{n=0}^{\infty}$, on $E \times E$ as follows : For $x, y \in E$,

$$\tilde{q}^0(x,y) := \begin{cases} 1 & \text{if } x = y, \\ 0 & \text{if } x \neq y; \end{cases} \quad \tilde{q}^1(x,y) := \tilde{q}(x,y), \quad \text{and}$$

$$\tilde{q}^{n+1}(x,y) := \sup_{z \in E}\{\tilde{q}^n(x,z) \wedge \tilde{q}(z,y)\} \quad n = 1,2,3,\cdots, \tag{2.2}$$

where the operation $\wedge$ means that $a \wedge b = \min\{a,b\}$ for real numbers a and b. Then, $\tilde{q}^n(x,y)$ means the possibility to transit from a point x to a point y at the nth step. The sequence of fuzzy state $\{\tilde{s}_n\}_{n=0}^{\infty}$ in (2.1) can be written as

$$\tilde{s}_n(y) = \sup_{x \in E}\{\tilde{s}_0(x) \wedge \tilde{q}^n(x,y)\}, \quad y \in E, \ n = 0,1,2,\cdots. \tag{2.3}$$

In this paper, we discuss the cyclic property of the fuzzy relations $\{\tilde{q}^n(x,y)\}_{n=0}^{\infty}$.

Let $x, y \in E$. For $\alpha \in (0,1]$, we write

$$x \underset{\alpha}{\rightsquigarrow} y \quad \text{if there exists a positive integer } n \text{ such that } \tilde{q}^n(x,y) \geq \alpha.$$

We also write

$$x \underset{0}{\rightsquigarrow} y \quad \text{if there exists a positive integer } n \text{ such that } \tilde{q}^n(x,y) > 0.$$

Definition 2.1. For $\alpha \in [0,1]$, we call a non-empty set $A(\subset E)$ α-essential if

$$x \underset{\alpha}{\rightsquigarrow} y \quad \text{and} \quad y \underset{\alpha}{\rightsquigarrow} x \quad \text{for all } x, y \in A.$$

We define $A_\alpha(x) := \{y \in E \mid x \rightsquigarrow_\alpha y \text{ and } y \rightsquigarrow_\alpha x\}$ for $x \in E$ and $\alpha \in [0,1]$. $A_\alpha(x)$ is clearly α-essential if it is not empty. Next we define

$$\mathbf{I}(x,\alpha) := \begin{cases} \{ \text{ positive integers } n \mid \tilde{q}^n(x,x) \geq \alpha\} & \text{for } x \in E, \ \alpha > 0, \\ \{ \text{ positive integers } n \mid \tilde{q}^n(x,x) > 0\} & \text{for } x \in E, \ \alpha = 0. \end{cases} \tag{2.4}$$

Then we put $d_{x,\alpha} := \gcd \mathbf{I}(x,\alpha)$ $(x \in E, \alpha \in [0,1])$, where gcd means the greatest common divisor of a set of positive integers. We call $d_{x,\alpha}$ a period of a state x with a level α. The following lemmas hold for $\alpha \in [0,1]$ and $x \in E$ such that $\mathbf{I}(x,\alpha) \neq \emptyset$.

Lemma 2.1.

(i) If $m, n \in \mathbf{I}(x,\alpha)$, then $m + n \in \mathbf{I}(x,\alpha)$.

2

(ii) *If $m \in I(x, \alpha)$, then $mn \in I(x, \alpha)$ for all positive integers n.*

Proof. (i) Let $\alpha > 0$ and $m, n \in I(x, \alpha)$. Then

$$\tilde{q}^{m+n}(x, x) = \sup_{y \in E}\{\tilde{q}^m(x, y) \wedge \tilde{q}^n(y, x)\} \geq \tilde{q}^m(x, x) \wedge \tilde{q}^n(x, x) \geq \alpha.$$

Therefore $m + n \in I(x, \alpha)$ and so (i) holds. We can easily check the case of $\alpha = 0$ similarly. (ii) is trivial from (i). $\square$

Lemma 2.2. *A family of periods, $\{d_{x,\alpha} \mid \alpha \in [0, 1]\}$, has the following properties :*

(i) $d_{x,\alpha'}$ *divides* $d_{x,\alpha}$ *if* $0 \leq \alpha' < \alpha \leq 1$,

(ii) *the map $\alpha(\in (0, 1]) \mapsto d_{x,\alpha}(\in \{1, 2, 3, \cdots\})$ is a non-decreasing left-continuous piecewise constant function.*

Proof. (i) Let α, α' satisfy $0 \leq \alpha' < \alpha \leq 1$. Since $I(x, \alpha') \supset I(x, \alpha)$, we have

$$\{d \mid d \text{ is a common devisor of } I(x, \alpha')\} \subset \{d \mid d \text{ is a common devisor of } I(x, \alpha)\}.$$

Therefore $d_{x,\alpha'} \leq d_{x,\alpha}$, and so $d_{x,\alpha'}$ divides $d_{x,\alpha}$.

(ii) From the definition of $I(x, \alpha)$, we have

$$\lim_{\alpha' \uparrow \alpha} I(x, \alpha') = \bigcap_{\alpha' < \alpha} I(x, \alpha') = I(x, \alpha).$$

Therefore $\lim_{\alpha' \uparrow \alpha} d_{x,\alpha'} = d_{x,\alpha}$. We obtain the assertion (ii) since the map $\alpha \mapsto d_{x,\alpha}$ takes discrete values. $\square$

We prepare several lemmas, referring [2, Theorems I.3.2 and I.3.3], to show the existence of cyclic classes for the dynamic fuzzy system.

Lemma 2.3. *If $x \rightsquigarrow_\alpha y$ and $y \rightsquigarrow_\alpha x$, then $d_{x,\alpha} = d_{y,\alpha}$.*

Proof. Let $\alpha > 0$. Since $x \rightsquigarrow_\alpha y$ and $y \rightsquigarrow_\alpha x$, there exist positive integers m and n such that $\tilde{q}^m(x, y) \geq \alpha$ and $\tilde{q}^n(y, x) \geq \alpha$. If $l \in I(x, \alpha)$, then

$$\tilde{q}^{n+l+m}(y, y) \geq \tilde{q}^n(y, x) \wedge \tilde{q}^l(x, x) \wedge \tilde{q}^m(x, y) \geq \alpha.$$

Therefore $n + l + m \in I(y, \alpha)$. Since $\tilde{q}^{2l}(x, x) \geq \tilde{q}^l(x, x) \wedge \tilde{q}^l(x, x) \geq \alpha$, we also have $n + 2l + m \in I(y, \alpha)$. So we obtain $l = (n + 2l + m) - (n + l + m) \equiv 0 \pmod{d_{y,\alpha}}$ for all $l \in I(x, \alpha)$. Therefore $d_{y,\alpha}$ divides $d_{x,\alpha}$. Similarly we can prove that $d_{x,\alpha}$ divides $d_{y,\alpha}$. Thus we obtain $d_{x,\alpha} = d_{y,\alpha}$. We can check the case of $\alpha = 0$ similarly. $\square$

Lemma 2.4. *Let $\alpha > 0$ and $y \in A_\alpha(x)$. Then there exists a unique integer $n_{x,y,\alpha}$ $(0 \leq n_{x,y,\alpha} < d_{x,\alpha})$ satisfying the following (i) :*

3

(i) if $\tilde{q}^m(x,y) \geq \alpha$, then $m \equiv n_{x,y,\alpha}$ (mod $d_{x,\alpha}$).

(ii) Further, there exists a positive integer $N_{x,y,\alpha}$ such that $\tilde{q}^{nd_{x,\alpha}+n_{x,y,\alpha}}(x,y) \geq \alpha$ for all $n \geq N_{x,y,\alpha}$.

Proof. (i) Let positive integers m and n satisfy $\tilde{q}^m(x,y) \geq \alpha$ and $\tilde{q}^n(x,y) \geq \alpha$. Let a positive integer l satisfy $\tilde{q}^l(y,x) \geq \alpha$. Then $\tilde{q}^{m+l}(x,x) \geq \tilde{q}^m(x,y) \wedge \tilde{q}^l(y,x) \geq \alpha$. Similarly $\tilde{q}^{n+l}(x,x) \geq \tilde{q}^n(x,y) \wedge \tilde{q}^l(y,x) \geq \alpha$. Therefore $m \equiv n$ (mod $d_{x,\alpha}$). Thus we obtain (i).

(ii) Let $n_i \in \mathbf{I}(x,\alpha)$ $(i = 1, 2, \cdots, k)$. From an elementary result of number theory, there exists $N'_{x,\alpha}$ such that for each positive integer n $(n \geq N'_{x,\alpha})$ there exist positive integers c_i $(i = 1, 2, \cdots, k)$ satisfying

$$nd_{x,\alpha} = \sum_{i=1}^{k} c_i n_i.$$

Then, from Lemma 2.1,

$$\tilde{q}^{nd_{x,\alpha}}(x,x) \geq \bigwedge_{i=1,2,\cdots,k} \tilde{q}^{c_i n_i}(x,x) \geq \alpha.$$

From (i), there exists a positive integer l such that $\tilde{q}^{ld_{x,\alpha}+n_{x,y,\alpha}}(x,y) \geq \alpha$. Put $N_{x,y,\alpha} := N'_{x,\alpha} + l$. For all $n \geq N_{x,y,\alpha}$, we obtain

$$\tilde{q}^{nd_{x,\alpha}+n_{x,y,\alpha}}(x,y) \geq \tilde{q}^{n'd_{x,\alpha}}(x,x) \wedge \tilde{q}^{md_{x,\alpha}+n_{x,y,\alpha}}(x,y) \geq \alpha,$$

where $n' := n - l \geq N'_{x,\alpha}$. Thus we get (ii). $\square$

We also have similar results for the case of $\alpha = 0$, which can be checked in the same way as Lemma 2.4.

Corollary 2.1. Let $y \in A_0(x)$. Then there exists a unique integer $n_{x,y,0}$ $(0 \leq n_{x,y,0} < d_{x,0})$ satisfying the following (i) :

(i) if $\tilde{q}^m(x,y) > 0$, then $m \equiv n_{x,y,0}$ (mod $d_{x,0}$).

(ii) Further there exists a positive integer $N_{x,y,0}$ such that $\tilde{q}^{nd_{x,0}+n_{x,y,0}}(x,y) > 0$ for all $n \geq N_{x,y,0}$.

Let $\alpha \in [0,1]$ and $x \in E$ satisfy $\mathbf{I}(x,\alpha) \neq \emptyset$. For a positive integer d, we put subsets of $A_\alpha(x)$ by

$$D_{\alpha,m}(x) := \begin{cases} \{y \in A_\alpha(x) \mid \tilde{q}^n(x,y) \geq \alpha \text{ for some } n \text{ satisfying } n \equiv m \text{ (mod } d)\} & \text{if } \alpha > 0, \\ \{y \in A_0(x) \mid \tilde{q}^n(x,y) > 0 \text{ for some } n \text{ satisfying } n \equiv m \text{ (mod } d)\} & \text{if } \alpha = 0, \end{cases}$$
$$(2.5)$$

4

for $m = 0, 1, 2 \cdots, d - 1$. If $\{D_{\alpha,n}(x)\}_{n=0,1,2\cdots,d-1}$ are disjoint and their union equals to $A_\alpha(x)$, then they are called subclasses of $A_\alpha(x)$ with the period d (c.f. [2, Section I.3]). For convenience, for $n \in \mathbf{N}$, we put

$$D_{\alpha,n}(x) := D_{\alpha,m}(x) \quad \text{if } n \equiv m \pmod{d}.$$

Now we define subsets of $A_\alpha(x)$ by

$$C_{\alpha,m}(x) := \begin{cases} \{y \in A_\alpha(x) \mid \tilde{q}^n(x,y) \geq \alpha \text{ for some } n \text{ satisfying } n \equiv m \pmod{d_{x,\alpha}}\} & \text{if } \alpha > 0, \\ \{y \in A_0(x) \mid \tilde{q}^n(x,y) > 0 \text{ for some } n \text{ satisfying } n \equiv m \pmod{d_{x,0}}\} & \text{if } \alpha = 0, \end{cases}$$
$$(2.6)$$

for $m = 0, 1, 2 \cdots, d_{x,\alpha} - 1$. From Lemma 2.4(i) and Corollary 2.1(i), $\{C_{\alpha,n}(x)\}_{n=0,1,2\cdots,d_{x,\alpha}-1}$ are subclasses of $A_\alpha(x)$ with the period $d_{x,\alpha}$.

We investigate a cyclic property for the dynamic fuzzy system (c.f. [2, Theorem I.3.4]). We use the following notations (see [3]) :

$$\tilde{q}_\alpha(x) := \{y \in E \mid \tilde{q}(x,y) \geq \alpha\} \quad \text{for } x \in E \text{ and } \alpha \in (0, 1].$$

For $\alpha \in (0, 1]$ and $x \in E$, we define a sequence of $\{\tilde{q}_\alpha^n(x)\}_{n=1}^\infty$ by

$$\tilde{q}_\alpha^1(x) := \tilde{q}_\alpha(x) \quad \text{and} \quad \tilde{q}_\alpha^{n+1}(x) := \bigcup_{y \in \tilde{q}_\alpha^n(x)} \tilde{q}_\alpha(y) \quad \text{for } n = 0, 1, 2, \cdots.$$

Definition 2.2 (c.f. [2]). For $\alpha \in (0, 1]$, we call a non-empty set $A(\subset E)$ α-closed if $\tilde{q}_\alpha(x) \subset A$ for all $x \in A$.

Definition 2.3 (c.f. [2, 4]). Subclasses $D_{\alpha,m}$ $(m = 0, 1, 2, \cdots, d - 1)$ with a period d are called cyclic classes if

$$\tilde{q}_\alpha^n(y) \subset D_{\alpha,m+n} \quad \text{for all } m = 0, 1, 2 \cdots, d - 1; \ n = 1, 2, 3 \cdots; \ y \in D_{\alpha,m}.$$

Theorem 2.1.

(i) If $y \in A_\alpha(x)$, then $A_\alpha(y) = A_\alpha(x)$ and $d_{y,\alpha} = d_{x,\alpha}$.

(ii) Let $m, n \in \mathbf{N}$. If $y \in C_{\alpha,m}(x)$, then $C_{\alpha,n}(y) = C_{\alpha,n+m}(x)$.

(iii) If $A_\alpha(x)$ is α-closed, then $C_{\alpha,m}(x)$ $(m = 0, 1, 2 \cdots, d_{x,\alpha} - 1)$ are cyclic classes.

Proof. (i) Let $y \in A_\alpha(x)$. Let $z \in A_\alpha(y)$. Since

$$x \underset{\alpha}{\rightsquigarrow} y \underset{\alpha}{\rightsquigarrow} z \quad \text{and} \quad z \underset{\alpha}{\rightsquigarrow} y \underset{\alpha}{\rightsquigarrow} x,$$

we obtain $z \in A_\alpha(x)$. Thus $A_\alpha(y) \subset A_\alpha(x)$. We obtain $A_\alpha(y) = A_\alpha(x)$ since the reverse inclusion can be checked similarly. We get (i) together with Lemma 2.3.

5

(ii) Let $y \in C_{\alpha,m}(x)$. Then we have

$$y \in A_\alpha(x) \quad \text{and} \quad \tilde{q}^{m'}(x,y) \geq \alpha \text{ for some } m' \text{ satisfying } m' \equiv m \pmod{d_{x,\alpha}}. \qquad (2.7)$$

For any $z \in C_{\alpha,n}(y)$, we have

$$z \in A_\alpha(y) \quad \text{and} \quad \tilde{q}^{n'}(y,z) \geq \alpha \text{ for some } n' \text{ satisfying } n' \equiv n \pmod{d_{y,\alpha}}.$$

By (i), this yields

$$z \in A_\alpha(x), \quad \tilde{q}^{n'}(y,z) \geq \alpha \quad \text{and} \quad n' \equiv n \pmod{d_{x,\alpha}}. \qquad (2.8)$$

Put $l := m' + m'$. Then $l \equiv n + m \pmod{d_{x,\alpha}}$. From (2.7) and (2.8),

$$\tilde{q}^l(x,z) = \tilde{q}^{n'+m'}(x,z) \geq \tilde{q}^{m'}(x,y) \wedge \tilde{q}^{n'}(y,z) \geq \alpha.$$

We obtain $z \in C_{\alpha,n+m}(x)$. Thus we get $C_{\alpha,n}(y) \subset C_{\alpha,n+m}(x)$. Further, since

$$\bigcup_{n=0,1,2\cdots,d_{y,\alpha}-1} C_{\alpha,n}(y) = A_\alpha(y) = A_\alpha(x) = \bigcup_{n=0,1,2\cdots,d_{x,\alpha}-1} C_{\alpha,n+m}(x),$$

we get (ii). We can prove the case of $\alpha = 0$ similarly.

(iii) Let $m = 0,1,2\cdots,d-1$, $n = 1,2,3\cdots$ and $y \in C_{\alpha,m}(x)$. Let $z \in \tilde{q}_\alpha^n(y)$. It is sufficient to check $z \in C_{\alpha,m+n}(x)$. Since $y \in A_\alpha(x)$ and $A_\alpha(x)$ is α-closed,

$$z \in \tilde{q}_\alpha^n(y) \subset A_\alpha(x). \qquad (2.9)$$

Since $\tilde{q}^n(y,z) \geq \alpha$ from $z \in \tilde{q}_\alpha^n(y)$, (2.9) and (ii) yield

$$z \in C_{\alpha,n}(y) = C_{\alpha,n+m}(x).$$

Therefore we get (iii). $\quad \square$

From Theorem 2.1, $\{C_{\alpha,n}(x)\}_{n=0,1,2\cdots,d_{x,\alpha}-1}$ does not depend on the choice of x. Therefore we denote it by $\{C_{\alpha,n}\}_{n=0,1,2\cdots,d_\alpha-1}$.

Lemma 2.5. *Let $x \in E$. If $\{D_{\alpha,m}\}_{m=0,1,2,\cdots,d-1}$ be subclasses of $A_\alpha(x)$ with a period d, then d divides d_α.*

Proof. Let $\alpha \in (0,1]$ and let $m \in \mathbf{I}(x,\alpha)$. Then $\tilde{q}^m(x,x) \geq \alpha$. Since $\{D_{\alpha,m}\}_{m=0,1,2,\cdots,d-1}$ are subclasses of $A_\alpha(x)$,

$$D_{\alpha,0} = \{y \in A_\alpha(x) \mid \tilde{q}^n(x,y) \geq \alpha \text{ for some } n \text{ satisfying } n \equiv 0 \pmod{d}\}.$$

By renumbering $\{D_{\alpha,m}\}_{m=0,1,2,\cdots,d-1}$ if necessary, we may assume that $C_{\alpha,0} \cap D_{\alpha,0} \neq \emptyset$. For $y \in C_{\alpha,0} \cap D_{\alpha,0}$, there exists n such that

$$\tilde{q}^n(x,y) \geq \alpha \quad \text{and} \quad n \equiv 0 \pmod{d}. \qquad (2.10)$$

6

Therefore $\tilde{q}^{m+n}(x,y) \geq \tilde{q}^m(x,x) \wedge \tilde{q}^n(x,y) \geq \alpha$. We have $m + n \equiv 0 \pmod{d}$ since $\{D_{\alpha,l}\}_{l=0,1,2,\cdots,d-1}$ are disjoint. Together with (2.10), we obtain $m \equiv 0 \pmod{d}$. Namely d divides all $m \in \mathbf{I}(x,\alpha)$. Thus d divides d_α. We can check the case of $\alpha = 0$ similarly. $\square$

Theorem 2.2. *Let $A_\alpha(x)$ be α-closed. Let $\{D_{\alpha,m}\}_{m=0,1,2,\cdots,d-1}$ be subclasses of $A_\alpha(x)$ with a period d. If $\{D_{\alpha,m}\}_{m=0,1,2,\cdots,d-1}$ are cyclic classes, then each $D_{\alpha,m}$ is the union of d_α/d sets from $\{C_{\alpha,n}\}_{n=0,1,2,\cdots,d_\alpha-1}$.*

Proof. With no loss of generality, we may assume that $x \in C_{\alpha,0} \cap D_{\alpha,0}$. Then $\{C_{\alpha,n} \cap D_{\alpha,m}\}_{n=0,1,2,\cdots,d_\alpha-1;m=0,1,2,\cdots,d-1}$ are subclasses of $A_\alpha(x)$ with a period $d_\alpha d$. Suppose that $C_{\alpha,m'} \cap D_{\alpha,m'} \neq C_{\alpha,m'}$ for some m'. Let $y \in C_{\alpha,m'} \backslash (C_{\alpha,m'} \cap D_{\alpha,m'})$. Since $y \notin (C_{\alpha,m'} \cap D_{\alpha,m'})$, we have

$$\tilde{q}^{ld_\alpha d+m'}(x,y) < \alpha \quad \text{for all } l = 1, 2, \cdots.$$

This contradicts $y \in C_{\alpha,m'}$. Therefore we obtain $C_{\alpha,m} \subset D_{\alpha,m}$ for all $m = 0, 1, \cdots, d-1$. Using the cyclic assumption for $\{D_{\alpha,m}\}_{m=0,1,2,\cdots,d-1}$, we have $C_{\alpha,m} \subset D_{\alpha,m} = D_{\alpha,n}$ if $0 \leq n < d_\alpha$ and $n \equiv m \pmod{d}$. Therefore $\bigcup_{l=0,1,2,\cdots,n'-1} C_{\alpha,ld+m} \subset D_{\alpha,m}$, where we put a positive integer $n' := d_\alpha/d$ from Lemma 2.5. Since

$$\bigcup_{m=0,1,2,\cdots,d-1} \bigcup_{l=0,1,2,\cdots,n'-1} C_{\alpha,ld+m} = A_\alpha = \bigcup_{m=0,1,2,\cdots,d-1} D_{\alpha,m},$$

we obtain $D_{\alpha,m} = \bigcup_{l=0,1,2,\cdots,n'-1} C_{\alpha,ld+m}$ for $m = 0, 1, 2, \cdots, d-1$. $\square$

3. An ergodic theorem

In this section, we consider the periodic limit of the sequence of the fuzzy transitions, $\{\tilde{q}^n(x,y)\}_{n=0}^\infty$, and discuss the ergodic property (c.f [2, Theorems I.6.1 and I.6.4]). Define

$$\alpha(x) := \sup_{n \geq 1} \tilde{q}^n(x,x) \quad \text{for } x \in E. \tag{3.1}$$

We put

$$A^* := \{x \in E \mid \alpha(x) > 0\} = \left\{ x \in E \mid \sup_{n \geq 1} \tilde{q}^n(x,x) > 0 \right\} = \{x \in E \mid x \in A_0(x)\}. \tag{3.2}$$

Then, A^* equals to the union of all positive recurrent sets (see [7, Theorem 3.1]). By the results of Section 2, we have the following limit theorem on A^* for the dynamic fuzzy system.

Theorem 3.1. *Let $x \in A^*$. Put*

$$d(x) := \lim_{\alpha \uparrow \alpha(x)} \gcd\{n \geq 1 \mid \tilde{q}^n(x,x) \geq \alpha\}.$$

If $d(x) < \infty$, then we have

$$\lim_{n \to \infty} \tilde{q}^{nd(x)}(x,x) = \alpha(x).$$

7

Proof. Let α satisfy $0 < \alpha < \alpha(x)$. Then $x \in A_\alpha(x)$. Therefore, there exists a period d_α of $A_\alpha(x)$. Let $\underline{\lambda}_\alpha := \underline{\lim}_{n \to \infty} \tilde{q}^{nd_\alpha}(x,x)$ and $\overline{\lambda}_\alpha := \overline{\lim}_{n \to \infty} \tilde{q}^{nd_\alpha}(x,x)$. From Lemma 2.4(ii), we have

$$\alpha \le \underline{\lambda}_\alpha \le \overline{\lambda}_\alpha \le \sup_{n \ge 1} \tilde{q}^n(x,x) = \alpha(x).$$

Therefore

$$\alpha(x) = \lim_{\alpha \uparrow \alpha(x)} \underline{\lambda}_\alpha = \lim_{\alpha \uparrow \alpha(x)} \overline{\lambda}_\alpha. \tag{3.3}$$

From Lemma 2.2(i), there exists a limit

$$d(x) := \lim_{\alpha \uparrow \alpha(x)} d_\alpha = \lim_{\alpha \uparrow \alpha(x)} \gcd\{n \ge 1 \mid \tilde{q}^n(x,x) \ge \alpha\}.$$

Suppose that $d(x) < \infty$. From (3.3) and Lemma 2.2(ii), we obtain

$$\alpha(x) = \lim_{\alpha \uparrow \alpha(x)} \underline{\lambda}_\alpha = \lim_{\alpha \uparrow \alpha(x)} \underline{\lim}_{n \to \infty} \tilde{q}^{nd_\alpha}(x,x) = \underline{\lim}_{n \to \infty} \lim_{\alpha \uparrow \alpha(x)} \tilde{q}^{nd_\alpha}(x,x) = \underline{\lim}_{n \to \infty} \tilde{q}^{nd(x)}(x,x).$$

Similarly we also have $\alpha(x) = \overline{\lim}_{n \to \infty} \tilde{q}^{nd(x)}(x,x)$. Therefore we get theorem. $\square$

Further, we need some notations in Yoshida [6, p.42] to describe the ergodic property. Put a path space by $\Omega := \prod_{n=0}^\infty E$ and write a path by $\omega = (\omega(0), \omega(1), \omega(2), \cdots) \in \Omega$. $\mathcal{M}$ denotes the σ-field generated by all Borel subsets of Ω. We define a map $X_n(\omega) := \omega(n)$ for $n \in \mathbf{N}$ and $\omega = (\omega(0), \omega(1), \omega(2), \cdots) \in \Omega$. Then $X_n(\omega)$ means a point at time n when the system transits along the path ω. For $y \in E$, the first hitting time of the point y is defined by

$$\sigma_{\{y\}}(\omega) := \inf\{n \ge 1 \mid X_n(\omega) = y\} \quad \omega \in \Omega,$$

where the infimum of the empty set is understood to be $+\infty$. For an initial state $x \in E$ and an $\mathcal{M}$-measurable fuzzy set $h \in \mathcal{F}(\Omega)$, we define a fuzzy expectation by

$$E_x(h) := \int_{\{\omega \in \Omega : \omega(0) = x\}} h(\omega) \, d\tilde{P}(\omega)$$

where $\tilde{P}$ is the following possibility measure :

$$\tilde{P}(\Lambda) := \sup_{\omega \in \Lambda} \bigwedge_{n \in \mathbf{N}} \tilde{q}(X_n\omega, X_{n+1}\omega) \qquad \Lambda \in \mathcal{M}$$

and $\int d\tilde{P}$ denotes Sugeno integral (Sugeno [5]). We also put $P_x(\Lambda) := E_x(1_\Lambda)$ for $\Lambda \in \mathcal{M}$ and $x \in E$. The fuzzy expectation is an extension of the fuzzy transition $\{\tilde{q}^n\}_{n=0}^\infty$ and admits stopping times depending on paths. We note that a possibility of transition from $x(\in E)$ to $y(\in E)$ at the nth step becomes $P_x(X_n = y) = \tilde{q}^n(x,y)$. Define the following possibilities :

$$\tilde{r}^m(x,y) := P_x(\sigma_{\{y\}} = m) \qquad m = 1, 2, \cdots; \ x, y \in E, \tag{3.4}$$

8

and
$$\gamma(x,y) := \sup_{m \geq 1} \tilde{r}^m(x,y) = P_x(\sigma_{\{y\}} < \infty) \quad x, y \in E. \tag{3.5}$$

Then, by [7, Proposition 2.1(ii)], we obtain

$$\gamma(x,y) = \sup_{m \geq 1} \tilde{q}^m(x,y).$$

Theorem 3.2. *Let* $y \in A^*$ *and* $y \in A_0(x)$ *such that* $d(y) < \infty$. *Then there exists a positive integer* $d(x,y)$, *which divides* $d(y)$, *and an integer* $n(x,y)$ $(0 \leq n(x,y) < d(x,y))$ *such that*
$$\lim_{n \to \infty} \tilde{q}^{nd(x,y)+n(x,y)}(x,y) = \gamma(x,y) \wedge \alpha(y).$$

Proof. For all $n = 1, 2, \cdots$, we have

$$\begin{aligned}
\tilde{q}^n(x,y) &= \max_{m=1,2,\cdots,n} \{\tilde{r}^m(x,y) \wedge \tilde{q}^{(n-m)}(y,y)\} \\
&\leq \sup_{m \geq 1} \tilde{r}^m(x,y) \wedge \sup_{l \geq 1} \tilde{q}^l(y,y) \\
&= \gamma(x,y) \wedge \alpha(y).
\end{aligned} \tag{3.6}$$

Let α satisfy $0 < \alpha < \gamma(x,y) \wedge \alpha(y)$. Then $y \in A_\alpha(x)$. From Lemma 2.4, there exists a positive integer $N_{x,y,\alpha}$ such that

$$\tilde{q}^{nd_{y,\alpha}+n_{x,y,\alpha}}(x,y) \geq \alpha \quad \text{for all } n \geq N_{x,y,\alpha}.$$

Together with (3.6), we have

$$\gamma(x,y) \wedge \alpha(y) \geq \varliminf_{n \to \infty} \tilde{q}^{nd_{y,\alpha}+n_{x,y,\alpha}}(x,y) \geq \alpha. \tag{3.7}$$

We define

$$d(x,y) := \lim_{\alpha \uparrow \gamma(x,y) \wedge \alpha(y)} d_{y,\alpha} \quad \text{and} \quad n(x,y) := \lim_{\alpha \uparrow \gamma(x,y) \wedge \alpha(y)} n_{x,y,\alpha}.$$

Then $d(x,y)$ divides $d(y)$ from Lemma 2.2(i) since $\alpha < \alpha(y)$. Letting $\alpha \uparrow \gamma(x,y) \wedge \alpha(y)$ in (3.7), in the same reason as the proof of Theorem 3.1, we obtain

$$\varliminf_{n \to \infty} \tilde{q}^{nd(x,y)+n(x,y)}(x,y) = \gamma(x,y) \wedge \alpha(y).$$

Similarly, we also have

$$\varlimsup_{n \to \infty} \tilde{q}^{nd(x,y)+n(x,y)}(x,y) = \gamma(x,y) \wedge \alpha(y).$$

Therefore we get this theorem. $\square$

Finally, we give an ergodic theorem regarding $\{\tilde{q}^m(x,y)\}_{m=1}^\infty$ for the dynamic fuzzy system. By Lemma 2.2, for $y \in A^*$ and $y \in A_0(x) = \bigcup_{\alpha > 0} A_\alpha(x)$ such that $d(y) < \infty$,

9

there exists a finite number of levels $\{\alpha_i \mid i = 0, 1, 2, \cdots, k\}$ satisfying the following (3.8)
and (3.9) :

$$0 = \alpha_0 < \alpha_1 < \alpha_2 < \cdots < \alpha_k = \alpha(y), \tag{3.8}$$

$$d_{y,\alpha} = \begin{cases} d_{y,\alpha_{i+1}} & \text{if } \alpha_i < \alpha \leq \alpha_{i+1} \text{ for } i \ (= 0, 1, 2, \cdots, k-2), \\ d(y) & \text{if } \alpha_{k-1} < \alpha < \alpha_k. \end{cases} \tag{3.9}$$

Further, there exists a positive integer k' $(k' \leq k)$ satisfying (3.10) and (3.11) :

$$\alpha_{k'-1} < \gamma(x,y) \wedge \alpha(y) \leq \alpha_{k'}, \tag{3.10}$$

$$d_{y,\alpha} = d(x,y) \quad \text{if } \alpha_{k'-1} < \alpha < \alpha_{k'}. \tag{3.11}$$

Then, by replacing $\alpha_{k'}$ by $\gamma(x,y) \wedge \alpha(y) \wedge \alpha_{k'}$, from Lemma 2.4(i) we have

$$n_{x,y,\alpha} = \begin{cases} n_{x,y,\alpha_{i+1}} & \text{if } \alpha_i < \alpha \leq \alpha_{i+1} \text{ for } i \ (= 0, 1, 2, \cdots, k'-2), \\ n(x,y) & \text{if } \alpha_{k'-1} < \alpha < \alpha_{k'}. \end{cases} \tag{3.12}$$

For simplicity, we write $d_i := d_{y,\alpha_i}$ and $n_i := n_{x,y,\alpha_i}$ for $i = 1, 2, \cdots, k'-1$ and we also
write $d_{k'} := d(x,y)$ and $n_{k'} := n(x,y)$.

Theorem 3.3 (ergodic theorem). *Let $x, y \in E$ satisfy $y \in A_0(x)$ and $d(y) < \infty$.*

(i) *If $y \notin A^*$, then*

$$\tilde{q}^m(x,y) = 0 \quad \text{for all } m = 1, 2, \cdots.$$

(ii) *If $y \in A^*$, then we have the following three cases :*

(a) *Case of $m \equiv n(x,y)$ (mod $d(x,y)$) :*

$$\lim_{n \to \infty} \tilde{q}^{nd(x,y)+n(x,y)}(x,y) = \gamma(x,y) \wedge \alpha(y).$$

(b) *Let $i = 1, 2, \cdots, k'-1$. Case of $m \not\equiv n_{i+1}$ (mod d_{i+1}) and $m \equiv n_i$ (mod d_i) :
There exists a positive integer N_i such that*

$$\tilde{q}^m(x,y) = \alpha_i \quad \text{for all } m \in \mathbf{J}(i) \text{ satisfying } m \geq N_i,$$

where $\mathbf{J}(i) := \{m \mid m \text{ is a positive integer satisfying } m \not\equiv n_{i+1}(\text{mod } d_{i+1}) \text{ and } m \equiv n_i(\text{mod } d_i)\}$.

(c) *Case of $m \not\equiv n_1$ (mod d_1) :*

$$\tilde{q}^m(x,y) = 0.$$

Proof. (i) If $y \notin A^*$, then $\alpha(y) = 0$. By (3.6), we get $\tilde{q}^m(x,y) = 0$ for all $m = 1, 2, \cdots$.
(ii.a) is from Theorem 3.2.
(ii.b) Let i satisfy $1 \leq i < k'$. Let α satisfy $\alpha_i < \alpha < \alpha_{i+1}$. From Lemmas 2.2(ii) and
2.4, we have

$$d_{y,\alpha} = d_{y,\alpha_{i+1}} = d_{i+1} \quad \text{and} \quad n_{x,y,\alpha} = n_{x,y,\alpha_{i+1}} = n_{i+1}. \tag{3.11}$$

10

From (3.11) and Lemma 2.4(i)(ii), there exists a positive integer N_i such that

$$\alpha_i \leq \tilde{q}^m(x,y) < \alpha \quad \text{for all } m \in \mathbf{J}(i) \text{ satisfying } m \geq N_i. \tag{3.12}$$

Since N_i depends only on x, y and α_{i+1}, letting $\alpha \downarrow \alpha_i$ in (3.12),

$$\tilde{q}^m(x,y) = \alpha_i \quad \text{for all } m \in \mathbf{J}(i) \text{ satisfying } m \geq N_i. \tag{3.13}$$

Therefore we get (ii.b).

(ii.c) Similarly to the proof of (ii.b), for $i = 0$, we get

$$\tilde{q}^m(x,y) = \alpha_0 = 0 \quad \text{for all } m \text{ satisfying } m \not\equiv n_1 (\text{mod } d_1).$$

Thus we obtain this theorem.   □

4. Numerical examples

We consider a one-dimensional numerical example with a one-dimensional state space $E = \mathbf{R}$, where $\mathbf{R}$ denotes the set of all real numbers. Then, $\tilde{q}_\alpha(x)$ are bounded closed intervals of $\mathbf{R}$ ($\alpha \in (0,1]$, $x \in \mathbf{R}$) and is written by $\tilde{q}_\alpha(x) = [\min \tilde{q}_\alpha(x), \max \tilde{q}_\alpha(x)]$, where $\min F$ ($\max F$) denotes the minimum (maximum resp.) point of a interval $F \subset \mathbf{R}$. We give a fuzzy relation, which is not monotone in the sense of [7], by

$$\tilde{q}(x,y) = (1 - |x + y^3|) \vee 0, \quad x, y \in \mathbf{R}. \tag{4.1}$$

Then $\tilde{q}(x,y)$ satisfies the conditions in Section 2 (see Figure 4.1).

Fig. 4.1 : The fuzzy relation $\tilde{q}(x,y)$.

In this paper, we call a set $\{x \in \mathbf{R} \mid \tilde{q}(x,x) = \alpha\}$ α-slice for each $\alpha \in [0,1]$. Figures 4.2 and 4.3 show its 0.7-slice and 0.5-slice respectively.

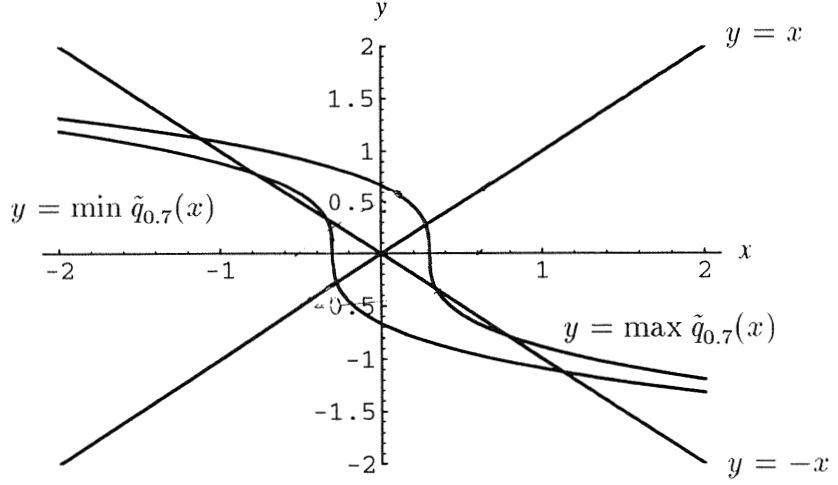

Fig. 4.2. The 0.7-slice $\{(x,y) \mid \tilde{q}(x,y) = 0.7\}$.

Fig. 4.3. The 0.5-slice $\{(x,y) \mid \tilde{q}(x,y) = 0.5\}$.

First, we consider the cyclic property in Section 2. In this example, we have

$$
\begin{aligned}
F_\alpha &:= \left\{ y \in \mathbf{R} \mid \sup_{n \geq 1} \tilde{q}^n(y,y) \geq \alpha \right\} = \{ y \in \mathbf{R} \mid \tilde{q}(y,y) \vee \tilde{q}^2(y,y) \geq \alpha \} \\
&= \{ x \in \mathbf{R} \mid \min \tilde{q}_\alpha(x) \leq -x \leq \max \tilde{q}_\alpha(x) \} \quad \text{for } \alpha \in (0,1].
\end{aligned}
\tag{4.2}
$$

Then $F_{0.5}$ is a closed interval. However, $F_{0.7}$ becomes a union of three closed intervals (see Figures 4.2 and 4.3). Therefore we write it by $F_{0.7} = F_{0.7,0} \cup F_{0.7,1} \cup F_{0.7,2}$. Calculating them, we have

$$
\begin{aligned}
F_{0.7,0} &\approx [-1.1254, -0.7865], \\
F_{0.7,1} &\approx [-0.3389, 0.3389], \\
F_{0.7,2} &\approx [0.7865, 1.1254],
\end{aligned}
$$

12

and

$$F_{0.5} \approx [-1.1915, 1.1915].$$

For $\alpha = 0.7$, $F_{0.7,1}$ and $F_{0.7,0} \cup F_{0.7,2}$ are 0.7-essential, which is 0.7-recurrent sets in the sense of Yoshida [7]. $F_{0.7,1}$ is not 0.7-closed. $F_{0.7,0} \cup F_{0.7,2}$ is 0.7-closed, and $F_{0.7,0}$ and $F_{0.7,2}$ are cyclic classes of $F_{0.7,0} \cup F_{0.7,2}$. The periods are

$$d_{y,0.7} = \begin{cases} 1 & \text{if } y \in F_{0.7,1}, \\ 2 & \text{if } y \in F_{0.7,0} \cup F_{0.7,2}, \end{cases} \tag{4.3}$$

For $\alpha = 0.5$, $F_{0.5}$ is 0.5-essential and 0.5-closed. We also have the period $d_{y,0.5} = 1$ for $y \in F_{0.5}$.

Next, we consider the ergodic property in Section 3. In this example, we have

$$\alpha(y) = \tilde{q}(y,y) \vee \tilde{q}^2(y,y) = (1 - |-y+y^3|) \vee 0 \quad \text{for } y \in \mathbf{R}. \tag{4.4}$$
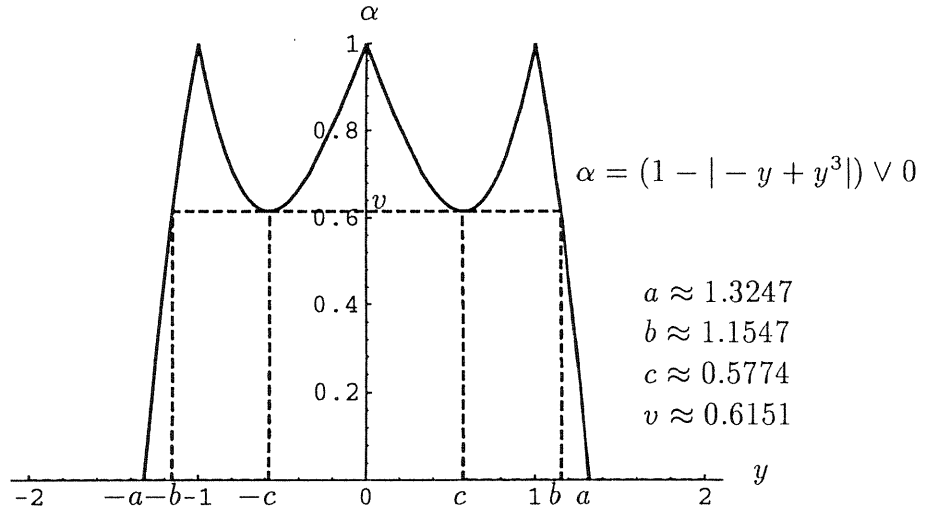

Figure 4.4 shows the graph.

Fig. 4.4. The graph of $\alpha = \alpha(y)$.

Then we put the union of all positive recurrent sets by

$$(-a, a) := A^* = \bigcup_{\alpha > 0} F_\alpha = \{y \in \mathbf{R} \mid \alpha(y) > 0\} \approx (-1.3247, 1.3247). \tag{4.5}$$

We also put

$$b := \frac{2}{\sqrt{3}} \approx 1.1547, \quad c := \frac{1}{\sqrt{3}} \approx 0.5774, \quad v := 1 - \frac{2}{3\sqrt{3}} \approx 0.6151.$$

From Figure 4.4, we obtain the following three cases (C.1), (C.2) and (C.3) :

(C.1) If $y \notin [-a, a]$, then

$$\tilde{q}^m(y,y) = 0 \quad \text{for all } m = 1, 2, \cdots.$$

13

(C.2) If $y \in (-b, -c) \cup (c, b)$, we may take

$$\alpha_0 = 0, \quad \alpha_1 = v, \quad \alpha_2 = (1 - |-y + y^3|) \vee 0, \tag{4.6}$$

$$d_{y,\alpha} = \begin{cases} d_1 = 1 & \text{if } \alpha_0 < \alpha \leq \alpha_1, \\ d_2 = 2 & \text{if } \alpha_1 < \alpha < \alpha_2. \end{cases} \tag{4.7}$$

Then we have the period $d(y) = 2$. By Theorem 3.3, we get the following cases :

(a) Case of $m \equiv 0 \pmod 2$:

$$\lim_{n \to \infty} \tilde{q}^{n \times 2}(y, y) = \alpha_2 = (1 - |-y + y^3|) \vee 0. \tag{4.8}$$

(b) Case of $m \equiv 1 \pmod 2$: There exists a positive integer N_1 such that

$$\tilde{q}^m(y, y) = \alpha_1 = v \quad \text{for all odd } m \text{ satisfying } m \geq N_1. \tag{4.9}$$

(C.3) If $y \in [-a, -b] \cup [-c, c] \cup [b, a]$, we may take

$$\alpha_0 = 0, \quad \alpha_1 = (1 - |-y + y^3|) \vee 0, \tag{4.10}$$

and $d_{y,\alpha} = d_1 = 1$ if $\alpha_0 < \alpha < \alpha_1$. Then we have the period $d(y) = 1$. By Theorem 3.3, we get

$$\lim_{m \to \infty} \tilde{q}^m(y, y) = \alpha_1 = (1 - |-y + y^3|) \vee 0. \tag{4.11}$$
