11 Running Head Title: Utilization of Natural Reservoir Brine
12

13 **Abstract**

14 This study aims to suggest the new approaches of enrichment cultures using natural
15 reservoir brine for enrichment culture medium in order to increase the bacterial population in the
16 enrichment cultures and isolate novel thermophilic anaerobic bacteria from an oil reservoir. The
17 results suggest that the brine-based culture medium should be sterilized by filtration to increase
18 the number of bacterial population and CO₂ should be supplied to culture medium to increase the
19 possibility of isolating novel bacteria from oil reservoirs. One of the specific bacteria isolated
20 under the presence of CO₂ was a strain AR80 representing a novel bacterium within the genus
21 *Petrotoga* on the basis of the phylogenetic analysis.
22

23 Keywords : reservoir brine, enrichment culture, isolation, CO₂, sterilization, novel bacteria

1 **Introduction**

2 The main focus of the previous studies of bacteria in oil reservoirs has primarily been related
3 to culture-based approaches, such as those reported by Ollivier and Cayol (2005). However,
4 according to Amann et al., (1995), approximately 85.0–99.9% of the total microbial community
5 in oil reservoirs is viable but non-culturable (VBNC) bacteria. Thus, since the number of
6 culturable bacteria is especially limited in oil reservoirs, culture-based approaches are
7 insufficient for clearly describing the in situ microbial communities present. The roles of VBNC
8 bacteria that have been detected in oil reservoirs by such techniques cannot be fully understood
9 until these bacteria become available as pure culture for detailed physiological and molecular
10 analyses. The lack of success in isolating not-yet-cultured bacteria from natural environments is
11 due to the physiology of these bacteria. It is important to meet the requirements for the growth of
12 these bacteria in enrichment cultures for the successful isolation; therefore, it is necessary to
13 develop new approaches and modifications of conventional microbiological techniques to isolate
14 not-yet-cultured bacteria from oil reservoirs.

15 In particular, the enrichment techniques are commonly used for isolating bacteria from
16 natural environments, and it duplicates closely the conditions of particular habitats (Madigan et
17 al., 2006). Enrichment techniques for isolating bacteria from oil reservoirs have been generally
18 carried out using synthetic mineral media in previous studies; however, most of reservoir
19 conditions can be easily duplicated using natural reservoir brine-based culture media (NBM) but
20 synthetic mineral media. In addition, gases such as CH₄ and CO₂ dissolve in brine under
21 reservoir conditions. The solubility of CO₂ in brine should be quite higher than that of CH₄ and
22 dissolving CO₂ causes the brine to become more acidic; therefore, the presence of CO₂ should be
23 taken into account as a reservoir condition in enrichment cultures.

1 This study aims to increase the bacterial population in enrichment cultures to isolate novel
2 bacteria from an oil reservoir by new approaches using natural reservoir brine for the enrichment
3 culture medium. For this purpose, the effect of the sterilization method for natural reservoir
4 brine-based culture medium to the increase in the bacterial population was considered. In
5 addition, the effect of the presence of CO₂, which was one of the reservoir conditions, to the
6 isolation of novel bacteria from an oil reservoir was also considered in this study.

7 **Materials and Methods**

8 **Enrichment Culture Experiments and Isolation of Thermophilic Anaerobic Bacteria**

9 The reservoir brine was extracted from a wellhead of an oil well in the Yabase Oilfield in
10 Akita, Japan. Enrichment culture experiments were carried out to isolate thermophilic anaerobic
11 bacteria, which were applicable to petroleum industrial applications such as Microbial EOR,
12 from the extracted sample. 0.1 ml of non-sterile brine was inoculated into 50 ml of culture
13 medium that consisted of sterile brine supplemented with 0.1 g/l yeast extract as a nitrogen
14 source and 2vol% of sterile crude oil as a carbon source for bacteria respectively. One set of
15 brine supplemented with yeast extract was sterilized through 0.22 µm sterile membrane filters,
16 whereas the other set was sterilized by autoclaving at 121°C for 20 minutes. The crude oil was
17 sterilized by autoclaving at the same conditions. Serum bottles containing the culture medium
18 were sealed with butyl rubber caps and aluminum crimps, and then the headspaces were replaced
19 with pure N₂, 10%-CO₂ (N₂ balanced), or pure CO₂. Enrichment culture experiments were
20 performed at 50°C without shaking.

21 After 1 week of incubation, bacteria were isolated from enrichment culture solutions by
22 Hungate roll-tube technique (Hungate, 1969) with slight modification. The enrichment culture
23 solution was inoculated into brine-based solid medium (BSM) solidified by 20 g/l of gellan gum.

1 The enrichment culture solution was also inoculated into a half concentration of solidified
2 reinforced clostridium medium (0.5×RCM; RCM0149, Oxoid Limited, UK) for control.
3 Approximately 50 ml of BSM or 0.5×RCM was poured in a serum bottle and the headspace was
4 replaced by each gas as described above. These preparations were sterilized by autoclaving at
5 121°C for 20 minutes. 0.1 ml of each enrichment culture solution was inoculated separately into
6 both media after they had been cooled down to 70°C, and was mixed before they had been
7 solidified. Two bottles were prepared for each condition.

8 After the solutions had been solidified at a slant, they were incubated at 50°C for 1–2 weeks.
9 After this time, significant increase in the number of colonies hadn't been observed. Each colony
10 whose size, pigmentation, margin and elevation were visually distinct were picked out from the
11 solid medium using sterile Pasteur pipettes in an anaerobic chamber degassed with pure N₂ (>
12 99.99%). The picked colonies had been transferred into fresh NBM in the anaerobic chamber.
13 The headspace of each serum bottle was replaced with each gas as described above. Each NBM
14 was incubated at 50°C for 3 weeks. The process of serial dilution was repeated at least twice in
15 order to purify the culture.

16 **Analyses of the Bacterial Populations in the Enrichment Culture Solutions**

17 The enrichment culture solution was filtered through 0.22 µm sterile membrane filters to
18 collect the bacterial cells on the filters. Total bacterial DNA was extracted from the filters and
19 purified using the Ultra Clean Soil DNA Isolation Kit (MO BIO Laboratories, Inc., USA)
20 according to the manufacturer's instructions.

21 A variable V3 region of the 16S rDNA gene of the purified DNA was amplified with nested
22 polymerase chain reaction (PCR) using Premix Taq™ Hot Start Version (Takara Bio Inc., Japan)
23 and primers. PCR conditions were carried out as described by Muyzer et al. (1993). The PCR

products were then applied to denaturing gradient gel electrophoresis (DGGE), and the bacterial diversities of the enrichment culture solutions were analyzed. The bacterial diversities of the enrichment culture solutions were evaluated based on the Shannon–Weaver diversity indices, which increase along with the increase in bacterial diversities, calculated using the DGGE results (Yeates et al., 2003). Homology searches of the DNA sequences were carried out using the GenBank DNA database (www.ncbi.nlm.nih.gov) with the BLAST program.

Identification of the Isolate

Preliminary characterization of the isolates was based on morphological observation of cells on an agar plate under both a phase contrast microscope (BH2; Olympus Corp., Japan) and a scanning electron microscope (JSM-6320F; JEOL Ltd., Japan). The isolate was also identified with molecular biology techniques. The identification of phylogenetic neighbors and pairwise 16S rRNA gene sequence similarities were calculated using the EzTaxon server (<http://www.eztaxon.org/>) (Chun et al., 2007). A phylogenic tree was constructed based on an alignment of the 16S rDNA with sequences of related genes from GenBank using the MEGA4 program (Tamura et al., 2007).

Results and Discussion

Microbial diversities of enrichment culture solutions are shown in Figure 1. The Shannon–Weaver diversity indices of the enrichment culture solutions that were sterilized by autoclaving and incubated in pure N₂, 10%-CO₂, or pure CO₂ atmosphere were 0.84, 0.68 and 0.37 respectively. On the other hand, those of the enrichment culture solutions that were sterilized by filtration and incubated under pure N₂, 10%-CO₂, or pure CO₂ atmosphere were 1.63, 1.22 and 0.96 respectively.

1 These results revealed that the diversity indices of filtrated enrichment culture solutions were
2 higher than those of autoclaved culture solutions. Although the autoclaving is the most common
3 and effective sterilization method, some elements and volatiles that are rich in natural reservoir
4 brine usually are lost by the excessive heat in these experiments. The results observed in these
5 experiments suggest that some composition of the natural reservoir brine was altered during
6 autoclaving. These alterations inhibited the growth of several bacteria that had inhabited the
7 brine originally; therefore, filtrated natural reservoir brine should be used for enrichment culture
8 medium to increase the bacterial population.

9 In both sterilization cases, the Shannon–Weaver diversity indices of the enrichment culture
10 solutions whose headspaces had been replaced by pure CO₂ were lower than those of other
11 enrichment culture solutions. These results indicate that the number of bacterial strains decreased
12 as the CO₂ concentration increased. This result was highly correlated with the pH of the
13 enrichment culture medium, which became 9.0, 8.5, and 7.2 after their headspaces were replaced
14 by pure N₂, 10%-CO₂, and pure CO₂ respectively. This result agrees with the results of a
15 previous study (Morozova et al. 2010) that showed that the number of microbial cells was
16 decreased from 2.4×10^6 cells/ml to 9.0×10^5 cells/ml just after CO₂ injection during a CO₂ storage
17 project in a saline aquifer.

18 The higher variety of bacterial composition was observed in the enrichment culture solution
19 that had been sterilized by filtration and incubated in pure N₂ atmosphere; however, two resultant
20 bands: Nos. 9 and 10 in Figure 1 were detected only under the presence of CO₂. These results
21 indicate that CO₂ may be useful in isolating novel bacterial strains from oil reservoirs. The pH
22 range for the growth of *Petrotoga* species that No. 10 was determined to be closely related to

1 was 6.5 to 8.0. These results suggest that the pH reduction of the culture medium due to the
2 dissolving CO₂ was effective in the screening of this kind of bacterium.

3 Nevertheless, the predominant bacterial population of the natural brine (i.e., Nos. 11, 12, and
4 13 in Figure 1) was not detected in the enrichment culture solutions. This result revealed that the
5 new approaches of enrichment cultures using natural reservoir brine developed in this study
6 effectively stimulated the growth of the bacteria that had naturally inhabited the reservoir as non-
7 dominant species.

8 To identify the bacterial communities in the enrichment culture solutions, sequence analyses
9 of 16S rDNA isolated from the DGGE gels were performed using the BLAST web program. The
10 predominant bacterium detected in all the enrichment culture solutions was similar (represented
11 by No. 6 in Figure 1), and was determined to be closely related to *Petrotoga mobilis* (92.5%
12 similarity). *Petrotoga* species have been found exclusively in oil reservoirs (Ollivier and Cayol,
13 2005), suggesting that they are native to high temperature and anaerobic environments; therefore,
14 the new approaches of enrichment cultures developed in this study could make a thermophilic
15 anaerobic bacterium a dominant successfully.

16 Based on the morphological appearance of the bacterial colonies, 7 kinds of bacteria had
17 been successfully isolated from the enrichment culture solutions after 1 week incubation (Table
18 1). The number of bacterial colonies isolated from incubation with 0.5×RCM was higher than
19 those from incubation with BSM. Many kinds of bacteria could form colonies and be isolated
20 with 0.5×RCM because it was abundant in simple carbon and nitrogen sources. On the other
21 hand, because BSM was poor in those substrates, the bacteria that could grow under substrate-
22 limited conditions could be isolated selectively with BSM. Furthermore, based on the previous
23 report by Ueda et al., (2008), it has been indicated that the enrichment cultivation approach with

1 a high level of CO₂ may enable the isolation of novel bacterial strains. According to these
2 considerations, only one isolated bacterium named AR80 could be expected to be a novel
3 bacterium because it formed its colonies only with BSM in pure CO₂ atmosphere. AR80 was
4 then further characterized.

5 As shown in Figure 2, the typical AR80 cell is rod-shaped, with a width of 0.25–0.75 µm
6 and a length of 2.5–7.0 µm, and has a characteristic outer sheath-like structure and polar flagella.
7 Complete nucleotide sequence of 16S rDNA of AR80 revealed that it is a member of the genus
8 *Petrotoga* with a similarity of 94.0% (GenBank accession number: GQ385331). Its closest
9 phylogenetic relationships were with *P. mobilis* (Lien et al., 1998), *P. sibirica*, *P. olearia*
10 (L'Haridon et al. 2002), and *P. Mexicana* (Miranda-Tello et al. 2004), which showed sequences
11 similarities of 94.7%, 94.2%, 94.4%, and 94.6% respectively (Figure 3). According to
12 Stackebrandt and Goebel (1994), 94.0% is a sufficiently low similarity to establish a new
13 species; therefore, AR80 is assumed to be a novel species within the genus *Petrotoga*.

14 **Conclusions**

15 This study aims to suggest new approaches of enrichment cultures using natural reservoir
16 brine to increase the bacterial population in enrichment cultures and isolate novel bacteria from
17 oil reservoirs. For this purpose, the effect of the sterilization method for natural reservoir brine-
18 based culture medium to the increase in the bacterial population was considered. In addition, the
19 effect of the presence of CO₂, which was one of the reservoir conditions, to the isolation of novel
20 bacteria from an oil reservoir was also considered. The following conclusions have been reached
21 in this study:

22 1) Natural reservoir brine-based culture medium should be sterilized by filtration to increase the
23 bacterial population in enrichment cultures of natural reservoir brine.

2) Presence of CO₂ in enrichment cultures is effective in increasing the possibility of isolating novel bacteria inhabiting oil reservoirs as non-dominant species.

3) A thermophilic anaerobic bacteria AR80 was isolated successfully through the new approaches of enrichment cultures developed in this study. According to the phylogenetic analyses, AR80 is a novel species belonging to the genus *Petrotoga*.

Thus, the new approaches of enrichment cultures developed in this study increase the possibility of isolating novel bacteria from oil reservoirs.

Acknowledgments

We gratefully acknowledge the financial support of Global Center of Excellence at Kyushu University. We are grateful to the INPEX Corporation of Japan for their cooperation in providing the brine samples. We are also grateful to Dr. K. Fujiwara for his technical supports in the DNA molecular techniques. We appreciate for the technical supports from the Research Support Center, Graduate School of Medical Sciences, Kyushu University for DNA sequencing analysis.
