Multi-poly-Bernoulli numbers and related zeta functions

Masanobu Kaneko* and Hirofumi Tsumura

Abstract

We construct and study a certain zeta function which interpolates multi-poly-Bernoulli numbers at non-positive integers and whose values at positive integers are linear combinations of multiple zeta values. This function can be regarded as the one to be paired up with the ξ -function defined by Arakawa and the first-named author. We show that both are closely related to the multiple zeta functions. Further we define multi-indexed poly-Bernoulli numbers, and generalize the duality formulas for poly-Bernoulli numbers by introducing more general zeta functions.

1. Introduction

In this paper, we investigate the function defined by

(1.1)
$$\eta(k_1, \dots, k_r; s) = \frac{1}{\Gamma(s)} \int_0^\infty t^{s-1} \frac{\operatorname{Li}_{k_1, \dots, k_r} (1 - e^t)}{1 - e^t} dt$$

and its generalizations, in connection with multi-poly-Bernoulli numbers and multiple zeta values (we shall give the precise definitions later in §2). This function can be viewed as a twin sibling of the function $\xi(k_1, \ldots, k_r; s)$,

(1.2)
$$\xi(k_1, \dots, k_r; s) = \frac{1}{\Gamma(s)} \int_0^\infty t^{s-1} \frac{\operatorname{Li}_{k_1, \dots, k_r} (1 - e^{-t})}{e^t - 1} dt,$$

which was introduced and studied in [4]. The present paper may constitute a natural continuation of the work [4].

To explain our results in some detail, we first give an overview of the necessary background. For an integer $k \in \mathbb{Z}$, two types of poly-Bernoulli numbers $\{B_n^{(k)}\}$ and $\{C_n^{(k)}\}$ are defined as follows (see Kaneko [20] and Arakawa-Kaneko [4], also Arakawa-Ibukiyama-Kaneko [3]):

(1.3)
$$\frac{\operatorname{Li}_k(1 - e^{-t})}{1 - e^{-t}} = \sum_{n=0}^{\infty} B_n^{(k)} \frac{t^n}{n!},$$

(1.4)
$$\frac{\operatorname{Li}_{k}(1 - e^{-t})}{e^{t} - 1} = \sum_{n=0}^{\infty} C_{n}^{(k)} \frac{t^{n}}{n!},$$

²⁰¹⁰ Mathematics Subject Classification: Primary 11B68; Secondary 11M32

Key words: multi-poly-Bernoulli number, multiple zeta value, Arakawa-Kaneko zeta function

where $\text{Li}_k(z)$ is the polylogarithm function defined by

(1.5)
$$\operatorname{Li}_{k}(z) = \sum_{m=1}^{\infty} \frac{z^{m}}{m^{k}} \quad (|z| < 1).$$

Since $\text{Li}_1(z) = -\log(1-z)$, we see that $B_n^{(1)}$ (resp. $C_n^{(1)}$) coincides with the ordinary Bernoulli number B_n defined by

$$\frac{te^t}{e^t - 1} = \sum_{n=0}^{\infty} B_n \frac{t^n}{n!} \qquad \left(\text{resp. } \frac{t}{e^t - 1} = \sum_{n=0}^{\infty} B_n \frac{t^n}{n!}\right).$$

A number of formulas, including closed formulas of $B_n^{(k)}$ and $C_n^{(k)}$ in terms of the Stirling numbers of the second kind as well as the duality formulas

(1.6)
$$B_n^{(-k)} = B_k^{(-n)},$$

(1.7)
$$C_n^{(-k-1)} = C_k^{(-n-1)}$$

that hold for $k, n \in \mathbb{Z}_{\geq 0}$, have been established (see [20, Theorems 1 and 2] and [21, §2]). We also mention that Brewbaker [9] gave a purely combinatorial interpretation of the number $B_n^{(-k)}$ of negative upper index as the number of 'Lonesum-matrices' with n rows and k columns.

A multiple version of $B_n^{(k)}$ is defined in [4, p. 202, Remarks (ii)] by

(1.8)
$$\frac{\operatorname{Li}_{k_1,\dots,k_r}(1-e^{-t})}{(1-e^{-t})^r} = \sum_{n=0}^{\infty} \mathbb{B}_n^{(k_1,\dots,k_r)} \frac{t^n}{n!} \quad (k_1,\dots,k_r \in \mathbb{Z}),$$

where

(1.9)
$$\operatorname{Li}_{k_1,\dots,k_r}(z) = \sum_{1 \le m_1 < \dots < m_r} \frac{z^{m_r}}{m_1^{k_1} m_2^{k_2} \cdots m_r^{k_r}}$$

is the multiple polylogarithm. Hamahata and Masubuchi [14, 15] investigated some properties of $\mathbb{B}_n^{(k_1,\dots,k_r)}$, and gave several generalizations of the known results in the single-index case. Based on this research, Bayad and Hamahata [8] further studied these numbers. Furusho [12, p. 269] also refers to (1.8).

More recently, Imatomi, Takeda and the first-named author [18] defined and studied another type of multi-poly-Bernoulli numbers given by

(1.10)
$$\frac{\operatorname{Li}_{k_1,\dots,k_r}(1-e^{-t})}{1-e^{-t}} = \sum_{n=0}^{\infty} B_n^{(k_1,\dots,k_r)} \frac{t^n}{n!},$$

(1.11)
$$\frac{\operatorname{Li}_{k_1,\dots,k_r}(1-e^{-t})}{e^t-1} = \sum_{n=0}^{\infty} C_n^{(k_1,\dots,k_r)} \frac{t^n}{n!}$$

for $k_1, \ldots, k_r \in \mathbb{Z}$. They proved several formulas for $B_n^{(k_1, \ldots, k_r)}$ and $C_n^{(k_1, \ldots, k_r)}$, and further gave an important relation between $C_{p-2}^{(k_1, \ldots, k_r)}$ and the 'finite multiple zeta value', that is,

(1.12)
$$\sum_{1 \le m_1 < \dots < m_r < p} \frac{1}{m_1^{k_1} \cdots m_r^{k_r}} \equiv -C_{p-2}^{(k_1, \dots, k_{r-1}, k_r - 1)} \mod p$$

for any prime number p.

The function (1.2) for $k_1, \ldots, k_r \in \mathbb{Z}_{\geq 1}$ can be analytically continued to an entire function of the complex variable $s \in \mathbb{C}$ ([4, Sections 3 and 4]). The particular case r = k = 1 gives $\xi(1;s) = s\zeta(s+1)$. Hence $\xi(k_1, \ldots, k_r; s)$ can be regarded as a multi-indexed zeta function. It is shown in [4] that the values at non-positive integers of $\xi(k;s)$ interpolate poly-Bernoulli numbers $C_m^{(k)}$,

(1.13)
$$\xi(k; -m) = (-1)^m C_m^{(k)}$$

for $k \in \mathbb{Z}_{\geq 1}$ and $m \in \mathbb{Z}_{\geq 0}$. And also by investigating $\xi(k_1, \ldots, k_r; s)$ and its values at positive integer arguments, one produces many relations among multiple zeta values defined by

(1.14)
$$\zeta(l_1, \dots, l_r) = \sum_{1 \le m_1 \le \dots \le m_r} \frac{1}{m_1^{l_1} \cdots m_r^{l_r}} \ (= \operatorname{Li}_{l_1, \dots, l_r}(1))$$

for $l_1, \ldots, l_r \in \mathbb{Z}_{\geq 1}$ with $l_r \geq 2$ ([4, Corollary 11]).

Recently, further properties of $\xi(k_1, \ldots, k_r; s)$ and related results have been given by several authors (see, for example, Bayad-Hamahata [6, 7], Coppo-Candelpergher [10], Sasaki [28], and Young [31]).

In this paper, we conduct a basic study of the function (1.1) and relate it to the multi-poly-Bernoulli numbers $B_n^{(k_1,\dots,k_r)}$ as well as multiple zeta (or 'zeta-star') values. Note that the only difference in both definitions (1.1) and (1.2) is, up to sign, the arguments $1 - e^t$ and $1 - e^{-t}$ of $\text{Li}_{k_1,\dots,k_r}(z)$ in the integrands. One sees in the main body of the paper a remarkable contrast between 'B-type' poly-Bernoulli numbers and those of 'C-type', and between multiple zeta and zeta-star values. We further investigate the case of non-positive indices k_i in connection with a yet more generalized 'multi-indexed' poly-Bernoulli number.

The paper is organized as follows. In §2, we give the analytic continuation of $\eta(k_1,\ldots,k_r;s)$ in the case of positive indices, and formulas for values at integer arguments (Theorems 2.3 and 2.5). In §3, we study relations between two functions $\eta(k_1,\ldots,k_r;s)$ and $\xi(k_1,\ldots,k_r;s)$ (Proposition 3.2), as well as relations with the single variable multiple zeta function (Definition 3.1 and Theorem 3.6). We turn in §4 to the study of $\eta(k_1,\ldots,k_r;s)$ in the negative index case and give a certain duality formula for $B_m^{(-k_1,\ldots,-k_r)}$ (Definition 4.3 and Theorems 4.4 and 4.7). We carry forward the study of negative index case in §5 and define the 'multi-indexed' poly-Bernoulli numbers $\{B_{m_1,\ldots,m_r}^{(k_1,\ldots,k_r),(d)}\}$ for $(k_1,\ldots,k_r) \in \mathbb{Z}^r$, $(m_1,\ldots,m_r) \in \mathbb{Z}^r_{\geq 0}$ and $d \in \{1,\ldots,r\}$ (Definition 5.1), which include (1.8) and (1.10) as special cases. We prove the 'multi-indexed' duality formula for them in the case d = r (Theorem 5.4).

2. The function $\eta(k_1, \ldots, k_r; s)$ for positive indices and its values at integers

2.1 Analytic continuation and the values at non-positive integers

We start with the definition in the case of positive indices.

Definition 2.1. For positive integers $k_1, \ldots, k_r \in \mathbb{Z}_{\geq 1}$, let

$$\eta(k_1, \dots, k_r; s) = \frac{1}{\Gamma(s)} \int_0^\infty t^{s-1} \frac{\text{Li}_{k_1, \dots, k_r} (1 - e^t)}{1 - e^t} dt$$

for $s \in \mathbb{C}$ with Re(s) > 1 - r, where $\Gamma(s)$ is the gamma function. When r = 1, we often denote $\eta(k; s)$ by $\eta_k(s)$.

The integral on the right-hand side converges absolutely in the domain Re(s) > 1 - r, as is seen from the following lemma.

Lemma 2.2. (i) For $k_1, \ldots, k_r \in \mathbb{Z}_{\geq 1}$, the function $\text{Li}_{k_1, \ldots, k_r} (1 - e^t)$ is holomorphic for $t \in \mathbb{C}$ with $|\text{Im}(t)| < \pi$.

(ii) For $k_1, \ldots, k_r \in \mathbb{Z}_{\geq 1}$ and $t \in \mathbb{R}_{\geq 0}$, we have the estimates

(2.1)
$$\operatorname{Li}_{k_1,\dots,k_r}(1-e^t) = O(t^r) \qquad (t \to 0)$$

and

(2.2)
$$\operatorname{Li}_{k_1,\dots,k_r}(1-e^t) = O\left(t^{k_1+\dots+k_r}\right) \qquad (t \to \infty).$$

Proof. As is well-known, we can regard the function $\text{Li}_{k_1,\dots,k_r}(z)$ as a single-valued holomorphic function in the simply connected domain $\mathbb{C} \setminus [1,\infty)$, via the process of iterated integration starting with $\text{Li}_1(z) = \int_0^z dz/(1-z)$. Noting that $1-e^t \in [1,\infty)$ is equivalent to $\text{Im}(t) = (2j+1)\pi$ for some $j \in \mathbb{Z}$, we have the assertion (i).

The estimate (2.1) is clear from the definition of $\text{Li}_{k_1,\dots,k_r}(z)$, because its Taylor series at z=0 starts with the term $z^r/1^{k_1}\cdots r^{k_r}$. As for (2.2), we proceed by induction on the 'weight' $k_1+\cdots+k_r$ as follows by using the formula

(2.3)
$$\frac{d}{dz} \operatorname{Li}_{k_1,\dots,k_r}(z) = \begin{cases} \frac{1}{z} \operatorname{Li}_{k_1,\dots,k_{r-1},k_r-1}(z) & (k_r > 1) \\ \frac{1}{1-z} \operatorname{Li}_{k_1,\dots,k_{r-1}}(z) & (k_r = 1), \end{cases}$$

which is easy to derive and is the basis of the analytic continuation of $\text{Li}_{k_1,\dots,k_r}(z)$ mentioned above. If $r = k_1 = 1$, then we have $\text{Li}_1(1 - e^t) = -t$ and the desired estimate holds. Suppose the weight k is larger than 1 and the assertion holds for any weight less than k. If $k_r > 1$, then by (2.3) we have

$$|\operatorname{Li}_{k_{1},\dots,k_{r}}(1-e^{t})| = \left| \int_{0}^{1-e^{t}} \frac{\operatorname{Li}_{k_{1},\dots,k_{r-1}}(u)}{u} du \right|$$

$$= \left| \int_{0}^{t} \frac{1}{1-e^{v}} \operatorname{Li}_{k_{1},\dots,k_{r-1}}(1-e^{v})(-e^{v}) dv \right| \qquad (u := 1-e^{v})$$

$$\leq \int_{0}^{\varepsilon} \left| e^{v} \frac{\operatorname{Li}_{k_{1},\dots,k_{r-1}}(1-e^{v})}{e^{v}-1} \right| dv + \int_{\varepsilon}^{t} \left| \frac{e^{v}}{e^{v}-1} \operatorname{Li}_{k_{1},\dots,k_{r-1}}(1-e^{v}) \right| dv$$

for small $\varepsilon > 0$. The former integral is O(1) because the integrand is continuous on $[0, \varepsilon]$. On the other hand, by induction hypothesis, the integrand of the latter integral is $O\left(v^{k_1+\cdots+k_r-1}\right)$ as $v \to \infty$. Therefore the latter integral is $O\left(t^{k_1+\cdots+k_r}\right)$ as $t \to \infty$. The case of $k_r = 1$ is similarly proved also by using (2.3), and is omitted here.

We now show that the function $\eta(k_1,\ldots,k_r;s)$ can be analytically continued to an entire function, and interpolates multi-poly-Bernoulli numbers $B_m^{(k_1,\ldots,k_r)}$ at non-positive integer arguments.

Theorem 2.3. For positive integers $k_1, \ldots, k_r \in \mathbb{Z}_{\geq 1}$, the function $\eta(k_1, \ldots, k_r; s)$ can be analytically continued to an entire function on the whole complex plane. And the values of $\eta(k_1, \ldots, k_r; s)$ at non-positive integers are given by

(2.4)
$$\eta(k_1, \dots, k_r; -m) = B_m^{(k_1, \dots, k_r)} \quad (m \in \mathbb{Z}_{\geq 0}).$$

In particular, $\eta_k(-m) = B_m^{(k)}$ for $k \in \mathbb{Z}_{\geq 1}$ and $m \in \mathbb{Z}_{\geq 0}$.

Proof. In order to prove this theorem, we adopt here the method of contour integral representation (see, for example, [30, Theorem 4.2]). Let \mathcal{C} be the standard contour, namely the path consisting of the positive real axis from the infinity to (sufficiently small) ε ('top side'), a counter clockwise circle C_{ε} around the origin of radius ε , and the positive real axis from ε to the infinity ('bottom side'). Let

$$H(k_1, \dots, k_r; s) = \int_{\mathcal{C}} t^{s-1} \frac{\text{Li}_{k_1, \dots, k_r} (1 - e^t)}{1 - e^t} dt$$
$$= (e^{2\pi i s} - 1) \int_{\varepsilon}^{\infty} t^{s-1} \frac{\text{Li}_{k_1, \dots, k_r} (1 - e^t)}{1 - e^t} dt + \int_{C_{\varepsilon}} t^{s-1} \frac{\text{Li}_{k_1, \dots, k_r} (1 - e^t)}{1 - e^t} dt.$$

It follows from Lemma 2.2 that $H(k_1, \ldots, k_r; s)$ is entire, because the integrand has no singularity on \mathcal{C} and the contour integral is absolutely convergent for all $s \in \mathbb{C}$. Suppose Re(s) > 1 - r. The last integral tends to 0 as $\varepsilon \to 0$. Hence

$$\eta(k_1, \dots, k_r; s) = \frac{1}{(e^{2\pi i s} - 1)\Gamma(s)} H(k_1, \dots, k_r; s),$$

which can be analytically continued to \mathbb{C} , and is entire. In fact $\eta(k_1, \ldots, k_r; s)$ is holomorphic for Re(s) > 0, hence has no singularity at any positive integer. Set $s = -m \in \mathbb{Z}_{\leq 0}$. Then, by (1.10),

$$\eta(k_1, \dots, k_r; -m) = \frac{(-1)^m m!}{2\pi i} H(k_1, \dots, k_r; -m)$$

$$= \frac{(-1)^m m!}{2\pi i} \int_{C_{\varepsilon}} t^{-m-1} \sum_{n=0}^{\infty} B_n^{(k_1, \dots, k_r)} \frac{(-t)^n}{n!} dt = B_m^{(k_1, \dots, k_r)}.$$

This completes the proof.

Remark 2.4. Using the same method as above or the method used in [4], we can establish the analytic continuation of $\xi(k_1, \ldots, k_r; s)$ to an entire function, and see that

(2.5)
$$\xi(k_1, \dots, k_r; -m) = (-1)^m C_m^{(k_1, \dots, k_r)} \quad (m \in \mathbb{Z}_{\geq 0})$$

for $k_1, \ldots, k_r \in \mathbb{Z}_{>1}$, which is a multiple version of (1.13).

2.2 Values at positive integers

About the values at positive integer arguments, we prove formulas for both $\xi(k_1, \ldots, k_r; s)$ and $\eta(k_1, \ldots, k_r; s)$, for general index (k_1, \ldots, k_r) . These formulas generalize [4, Theorem 9 (i)], and have remarkable similarity in that one obtains the formula for $\eta(k_1, \ldots, k_r; s)$ just by replacing

multiple zeta values in the one for $\xi(k_1, \ldots, k_r; s)$ with multiple 'zeta-star' values. Recall the multiple zeta-star value is a real number defined by

(2.6)
$$\zeta^{\star}(l_1, \dots, l_r) = \sum_{1 < m_1 < \dots < m_r} \frac{1}{m_1^{l_1} \cdots m_r^{l_r}}$$

for $l_1, \ldots, l_r \in \mathbb{Z}_{\geq 1}$ with $l_r \geq 2$. This was first studied (for general r) by Hoffman in [16].

To state our theorem, we further introduce some notation. For an index set $\mathbf{k} = (k_1, \dots, k_r) \in \mathbb{Z}_{\geq 1}^r$, put $\mathbf{k}_+ = (k_1, \dots, k_{r-1}, k_r + 1)$. The usual dual index of an *admissible* index (i.e. the one that the last entry is greater than one) \mathbf{k} is denoted by \mathbf{k}^* . For $\mathbf{j} = (j_1, \dots, j_r) \in \mathbb{Z}_{\geq 0}^r$, we write $|\mathbf{j}| = j_1 + \dots + j_r$ and call it the weight of \mathbf{j} , and $d(\mathbf{j}) = r$, the depth of \mathbf{j} . For two such indices \mathbf{k} and \mathbf{j} of the same depth, we denote by $\mathbf{k} + \mathbf{j}$ the index obtained by the component-wise addition, $\mathbf{k} + \mathbf{j} = (k_1 + j_1, \dots, k_r + j_r)$, and by $b(\mathbf{k}; \mathbf{j})$ the quantity given by

$$b(\mathbf{k}; \mathbf{j}) := \prod_{i=1}^{r} \binom{k_i + j_i - 1}{j_i}.$$

Theorem 2.5. For any index set $\mathbf{k} = (k_1, \dots, k_r) \in \mathbb{Z}_{\geq 1}^r$ and any $m \in \mathbb{Z}_{\geq 1}$, we have

(2.7)
$$\xi(k_1,\ldots,k_r;m) = \sum_{|\mathbf{j}|=m-1,\,d(\mathbf{j})=n} b((\mathbf{k}_+)^*;\mathbf{j})\,\zeta((\mathbf{k}_+)^*+\mathbf{j})$$

and

(2.8)
$$\eta(k_1, \dots, k_r; m) = (-1)^{r-1} \sum_{|\mathbf{j}| = m-1, d(\mathbf{j}) = n} b((\mathbf{k}_+)^*; \mathbf{j}) \, \zeta^*((\mathbf{k}_+)^* + \mathbf{j}),$$

where both sums are over all $\mathbf{j} \in \mathbb{Z}_{\geq 0}^r$ of weight m-1 and depth $n := d(\mathbf{k}_+^*)$ $(= |\mathbf{k}| + 1 - d(\mathbf{k}))$. In particular, we have

$$\xi(k_1,\ldots,k_r;1)=\zeta((\mathbf{k}_+)^*) \quad (=\zeta(\mathbf{k}_+), \text{ by the duality of multiple zeta values})$$

and

$$\eta(k_1,\ldots,k_r;1) = (-1)^{r-1} \zeta^*((\mathbf{k}_+)^*).$$

In order to prove the theorem, we give certain multiple integral expressions of the functions $\xi(k_1,\ldots,k_r;s)$ and $\eta(k_1,\ldots,k_r;s)$.

Proposition 2.6. Notations being as above, write $(\mathbf{k}_+)^* = (l_1, \dots, l_n)$. Then we have, for $\operatorname{Re}(s) > 1 - r$,

(i)
$$\xi(k_1, \dots, k_r; s) = \frac{1}{\prod_{i=1}^n \Gamma(l_i) \cdot \Gamma(s)} \int_0^\infty \dots \int_0^\infty (x_1 + \dots + x_n)^{s-1} x_1^{l_1 - 1} \dots x_n^{l_n - 1} \times \frac{1}{e^{x_1 + \dots + x_n - 1}} \cdot \frac{1}{e^{x_2 + \dots + x_n - 1}} \dots \frac{1}{e^{x_n - 1}} dx_1 \dots dx_n.$$

(ii)
$$\eta(k_1, \dots, k_r; s) = \frac{(-1)^{r-1}}{\prod_{i=1}^n \Gamma(l_i) \cdot \Gamma(s)} \int_0^\infty \dots \int_0^\infty (x_1 + \dots + x_n)^{s-1} x_1^{l_1 - 1} \dots x_n^{l_n - 1} \times \frac{1}{e^{x_1 + \dots + x_n} - 1} \cdot \frac{e^{x_2 + \dots + x_n}}{e^{x_2 + \dots + x_n} - 1} \dots \frac{e^{x_n}}{e^{x_n} - 1} dx_1 \dots dx_n.$$

Proof. First write the index (k_1, \ldots, k_r) as

$$(k_1,\ldots,k_r) = (\underbrace{1,\ldots,1}_{a_1-1},b_1+1,\ldots,\underbrace{1,\ldots,1}_{a_h-1},b_h+1),$$

with (uniquely determined) integers $h \ge 1$, $a_i \ge 1$ $(1 \le i \le h)$, $b_i \ge 1$ $(1 \le i \le h-1)$, and $b_h \ge 0$. Then, by performing the intermediate integrals of repeated dz/(1-z) in the standard iterated integral coming from (2.3), we obtain the following iterated integral expression of the multiple polylogarithm $\text{Li}_{k_1,\ldots,k_r}(z)$:

$$\operatorname{Li}_{k_{1},\dots,k_{r}}(z) = \underbrace{\int_{0}^{z} \frac{dx_{h}}{x_{h}} \int_{0}^{x_{h}} \dots \int_{0}^{x_{h}} \frac{dx_{h}}{x_{h}} \int_{0}^{x_{h}} \frac{1}{a_{h}!} \log\left(\frac{1-x_{h-1}}{1-x_{h}}\right)^{a_{h}} \frac{dx_{h-1}}{x_{h-1}}}_{b_{h}} \cdot \underbrace{\int_{0}^{x_{h-1}} \frac{dx_{h-1}}{x_{h-1}} \dots \int_{0}^{x_{h-1}} \frac{dx_{h-1}}{x_{h-1}} \int_{0}^{x_{h-1}} \frac{1}{a_{h-1}!} \log\left(\frac{1-x_{h-2}}{1-x_{h-1}}\right)^{a_{h-1}} \frac{dx_{h-2}}{x_{h-2}} \cdot \dots \cdot \underbrace{\int_{0}^{x_{h}} \frac{dx_{h}}{x_{h}} \dots \int_{0}^{x_{h}} \frac{dx_{h}}{x_{h}} \int_{0}^{x_{h}} \frac{1}{a_{h}!} \log\left(\frac{1-x_{h}}{1-x_{h}}\right)^{a_{h}} \frac{dx_{h}}{x_{h-1}} \cdot \dots \cdot \underbrace{\int_{0}^{x_{h}} \frac{dx_{h}}{x_{h}} \int_{0}^{x_{h-1}} \frac{1}{a_{h-1}!} \log\left(\frac{1-x_{h-2}}{1-x_{h-1}}\right)^{a_{h-1}} \frac{dx_{h-2}}{x_{h-2}} \cdot \dots \cdot \underbrace{\int_{0}^{x_{h}} \frac{dx_{h}}{x_{h}} \int_{0}^{x_{h}} \frac{1}{a_{h}!} \log\left(\frac{1-x_{h}}{1-x_{h}}\right)^{a_{h}} \frac{dx_{h}}{x_{h-1}} \cdot \underbrace{\int_{0}^{x_{h}} \frac{dx_{h}}{x_{h}} \int_{0}^{x_{h}} \frac{1}{a_{h}!} \log\left(\frac{1-x_{h-2}}{1-x_{h}}\right)^{a_{h}} \frac{dx_{h}}{x_{h-2}} \cdot \dots \cdot \underbrace{\int_{0}^{x_{h}} \frac{dx_{h}}{x_{h}} \int_{0}^{x_{h}} \frac{1}{a_{h}!} \log\left(\frac{1-x_{h}}{1-x_{h}}\right)^{a_{h}} \frac{dx_{h}}{x_{h-1}} \cdot \dots \cdot \underbrace{\int_{0}^{x_{h}} \frac{dx_{h}}{x_{h}} \int_{0}^{x_{h}} \frac{dx_{h}}{x_{h-1}} \frac{1}{x_{h-1}} \log\left(\frac{1-x_{h}}{1-x_{h}}\right)^{a_{h}} \frac{dx_{h}}{x_{h-1}} \cdot \dots \cdot \underbrace{\int_{0}^{x_{h}} \frac{dx_{h}}{x_{h}} \int_{0}^{x_{h}} \frac{dx_{h}}{x_{h}} \frac{1}{x_{h-1}} \log\left(\frac{1-x_{h}}{1-x_{h}}\right)^{a_{h}} \frac{dx_{h}}{x_{h-1}} \cdot \dots \cdot \underbrace{\int_{0}^{x_{h}} \frac{dx_{h}}{x_{h}} \int_{0}^{x_{h}} \frac{dx_{h}}{x_{h}} \frac{1}{x_{h}} \frac{dx_{h}}{x_{h}} \cdot \dots \cdot \underbrace{\int_{0}^{x_{h}} \frac{dx_{h}}{x_{h}} \frac{1}{x_{h}} \frac{dx_{h}}{x_{h}} \frac{1}{x_{h}} \cdot \dots \cdot \underbrace{\int_{0}^{x_{h}} \frac{dx_{h}}{x_{h}} \frac{1}{x_{h}} \frac{dx_{h}}{x_{h}} \frac{1}{x_{h}} \frac{dx_{h}}{x_{h}} \frac{1}{x_{h}} \frac{1$$

Here, to ease notation, we used the same variable in the repetitions of integrals $\int_0^x dx/x$, and we understand $x_h = z$ if $b_h = 0$. The paths of integrations are in the domain $\mathbb{C} \setminus [1, \infty)$, and the formula is valid for $z \in \mathbb{C} \setminus [1, \infty)$. We may check this formula by differentiating both sides repeatedly and using (2.3). Putting $z = 1 - e^{-t}$ and $1 - e^{t}$, changing variables accordingly, and suitably labeling the variables, we obtain

suitably labeling the variables, we obtain
$$(2.9) \quad \text{Li}_{k_1,\dots,k_r}(1-e^{-t}) = \int_0^t \int_0^{t_{b_1}+\dots+b_h} \cdots \int_0^{t_2} \underbrace{\frac{1}{e^{t_{b_1}+\dots+b_h}-1} \cdots \frac{1}{e^{t_{b_1}+\dots+b_{h-1}+2}-1}}_{b_h-1} \\ \times \frac{1}{a_h!} \underbrace{\frac{(t_{b_1}+\dots+b_{h-1}+1}-t_{b_1}+\dots+b_{h-1})^{a_h}}{e^{t_{b_1}+\dots+b_{h-1}+1}-1}} \cdot \underbrace{\frac{1}{e^{t_{b_1}+\dots+b_{h-1}}-1} \cdots \frac{1}{e^{t_{b_1}+\dots+b_{h-1}}-1}}}_{b_h-1} \\ \times \cdots \cdots \\ \times \frac{1}{a_3!} \underbrace{\frac{(t_{b_1}+b_2+1}-t_{b_1}+b_2)^{a_3}}{e^{t_{b_1}+b_2+1}-1}} \cdot \underbrace{\frac{1}{e^{t_{b_1}+b_2}-1} \cdots \frac{1}{e^{t_{b_1}+b_2}-1}}}_{b_2-1} \\ \times \frac{1}{a_2!} \underbrace{\frac{(t_{b_1+1}-t_{b_1})^{a_2}}{e^{t_{b_1+1}}-1}} \cdot \underbrace{\frac{1}{e^{t_{b_1}-1}} \cdots \frac{1}{e^{t_2}-1}}_{b_1-1} \cdot \underbrace{\frac{1}{a_1!} \underbrace{\frac{t_{a_1}^{a_1}}{e^{t_1}-1}} dt_1 dt_2 \cdots dt_{b_1+\dots+b_h}}_{dt_1+\dots+b_h},$$

and

(2.10)

(2.10)
$$\operatorname{Li}_{k_1,\dots,k_r}(1-e^t) = (-1)^r \int_0^t \int_0^{t_{b_1+\dots+b_h}} \dots \int_0^{t_2} \underbrace{\frac{e^{t_{b_1+\dots+b_h}}}{e^{t_{b_1+\dots+b_h}} - 1} \dots \underbrace{\frac{e^{t_{b_1+\dots+b_{h-1}+2}}}{e^{t_{b_1+\dots+b_{h-1}+2}} - 1}}_{b_h-1}$$

$$\times \frac{1}{a_{h}!} \frac{(t_{b_{1}+\cdots+b_{h-1}+1}-t_{b_{1}+\cdots+b_{h-1}})^{a_{h}} e^{t_{b_{1}+\cdots+b_{h-1}+1}}}{e^{t_{b_{1}+\cdots+b_{h-1}+1}}-1} \cdot \underbrace{\frac{e^{t_{b_{1}+\cdots+b_{h-1}}}}{e^{t_{b_{1}+\cdots+b_{h-1}}}-1} \cdots \underbrace{\frac{e^{t_{b_{1}+\cdots+b_{h-1}}}}{e^{t_{b_{1}+\cdots+b_{h-2}+2}}-1}}_{b_{h-1}-1}$$

$$\times \cdots \times \frac{1}{a_{3}!} \frac{(t_{b_{1}+b_{2}+1} - t_{b_{1}+b_{2}})^{a_{3}} e^{t_{b_{1}+b_{2}+1}}}{e^{t_{b_{1}+b_{2}+1}} - 1} \cdot \underbrace{\frac{e^{t_{b_{1}+b_{2}}}}{e^{t_{b_{1}+b_{2}}} - 1} \cdots \frac{e^{t_{b_{1}+2}}}{e^{t_{b_{1}+2}} - 1}}_{b_{2}-1} \times \underbrace{\frac{1}{a_{2}!} \frac{(t_{b_{1}+1} - t_{b_{1}})^{a_{2}} e^{t_{b_{1}+1}}}{e^{t_{b_{1}+1}}}}_{b_{1}-1} \cdot \underbrace{\frac{e^{t_{b_{1}}}}{e^{t_{b_{1}}} - 1} \cdots \frac{e^{t_{2}}}{e^{t_{2}} - 1}}_{b_{1}-1} \cdot \underbrace{\frac{1}{a_{1}!} \frac{t_{1}^{a_{1}} e^{t_{1}}}{e^{t_{1}} - 1}}_{dt_{1} dt_{2} \cdots dt_{b_{1}+\cdots+b_{h}}}.$$

The factor $(-1)^r$ on the right of (2.10) comes from $(-1)^{a_1+\cdots+a_h}=(-1)^r$. Plugging (2.9) and (2.10) into the definitions (1.2) and (1.1) respectively and making the change of variables

$$t = x_1 + \dots + x_n, \ t_{b_1 + \dots + b_h} = x_2 + \dots + x_n, \ t_{b_1 + \dots + b_h - 1} = x_3 + \dots + x_n, \dots, t_2 = x_{n-1} + x_n, \ t_1 = x_n,$$

we obtain the proposition. One should note that the dual index $(\mathbf{k}_+)^* = (l_1, \dots, l_n)$ is given by

$$(\mathbf{k}_{+})^{*} = (\underbrace{1, \dots, 1}_{b_{h}}, a_{h} + 1, \underbrace{1, \dots, 1}_{b_{h-1}-1}, a_{h-1} + 1, \dots, \underbrace{1, \dots, 1}_{b_{1}-1}, a_{1} + 1)$$

and the depth n is equal to $b_1 + \cdots + b_h + 1$, and that (the trivial) $x_i^{l_i-1} = 1$ when $l_i = 1$.

Proof of Theorem 2.5. Set s = m in the integral expressions in the proposition, and expand $(x_1 + \cdots + x_k)^{m-1}$ by the multinomial theorem. Then the formula in the theorem follows from the lemma below.

Lemma 2.7. For $l_1, \ldots, l_r \in \mathbb{Z}_{\geq 1}$ with $l_r \geq 2$, we have

$$\zeta(l_1, \dots, l_r) = \frac{1}{\prod_{i=1}^r \Gamma(l_i)} \int_0^\infty \dots \int_0^\infty \frac{x_1^{l_1 - 1} \dots x_r^{l_r - 1}}{e^{x_1 + \dots + x_r} - 1} \cdot \frac{1}{e^{x_2 + \dots + x_r} - 1} \dots \frac{1}{e^{x_r} - 1} dx_1 \dots dx_r$$

and

$$\zeta^{*}(l_{1},\ldots,l_{r}) = \frac{1}{\prod_{j=1}^{r} \Gamma(l_{j})} \int_{0}^{\infty} \cdots \int_{0}^{\infty} \frac{x_{1}^{l_{1}-1} \cdots x_{r}^{l_{r}-1}}{e^{x_{1}+\cdots+x_{r}}-1} \cdot \frac{e^{x_{2}+\cdots+x_{r}}}{e^{x_{2}+\cdots+x_{r}}-1} \cdots \frac{e^{x_{r}}}{e^{x_{r}}-1} dx_{1} \cdots dx_{r}.$$

Proof. The first formula is given in [4, Theorem 3 (i)]. As for the second, we may proceed similarly by using $n^{-s} = \Gamma(s)^{-1} \int_0^\infty t^{s-1} e^{-nt} dt$ to have

$$\zeta^{*}(l_{1},\ldots,l_{r}) = \sum_{m_{1}=1}^{\infty} \sum_{m_{2},\ldots,m_{r}=0}^{\infty} \frac{1}{m_{1}^{l_{1}}(m_{1}+m_{2})^{l_{2}}\cdots\cdots(m_{1}+\cdots+m_{r})^{l_{r}}}
= \frac{1}{\prod_{j=1}^{r} \Gamma(l_{j})} \sum_{m_{1}=1}^{\infty} \sum_{m_{2},\ldots,m_{r}=0}^{\infty} \int_{0}^{\infty} \cdots \int_{0}^{\infty} x_{1}^{l_{1}-1} e^{-m_{1}x_{1}} \cdot x_{2}^{l_{2}-1} e^{-(m_{1}+m_{2})x_{2}} \cdots
\cdots x_{r}^{l_{r}-1} e^{-(m_{1}+\cdots+m_{r})x_{r}} dx_{1} \cdots dx_{r}
= \frac{1}{\prod_{j=1}^{r} \Gamma(l_{j})} \sum_{m_{1}=1}^{\infty} \sum_{m_{2}=0}^{\infty} \int_{0}^{\infty} \cdots \int_{0}^{\infty} x_{1}^{l_{1}-1} \cdots x_{r}^{l_{r}-1} e^{-m_{1}(x_{1}+\cdots+x_{r})} \cdot e^{-m_{2}(x_{2}+\cdots+x_{r})} \cdots$$

$$= \frac{1}{\prod_{j=1}^{r} \Gamma(l_{j})} \int_{0}^{\infty} \cdots \int_{0}^{\infty} \frac{x_{1}^{l_{1}-1} \cdots x_{r}^{l_{r}-1}}{e^{x_{1}+\cdots+x_{r}}-1} \cdot \frac{e^{x_{2}+\cdots+x_{r}}}{e^{x_{2}+\cdots+x_{r}}-1} \cdots \frac{e^{x_{r}}}{e^{x_{r}}-1} dx_{1} \cdots dx_{r}.$$

We record here one corollary to the theorem in the case of $\eta_k(m)$ (compare with the similar formula in [4, Theorem 9 (i)]). Noting $(k+1)^* = (\underbrace{1,\ldots,1}_{k-1},2)$, we have

Corollary 2.8. For $k, m \ge 1$, we have

(2.11)
$$\eta_k(m) = \sum_{\substack{j_1, \dots, j_{k-1} \ge 1, j_k \ge 2\\ j_1 + \dots + j_k = k+m}} (j_k - 1) \zeta^*(j_1, \dots, j_{k-1}, j_k).$$

3. Relations among the functions ξ , η and ζ , and their consequences to multiple zeta values and multi-poly-Bernoulli numbers

In this section, we first deduce that each of the functions η and ξ can be written as a linear combination of the other by the *same* formula. This is a consequence of the so-called Landen-type connection formula for the multiple polylogarithm $\text{Li}_{k_1,\ldots,k_r}(z)$. We then establish a formula for $\xi(k_1,\ldots,k_r;s)$ in terms of the single-variable multiple zeta function

(3.1)
$$\zeta(l_1, \dots, l_r; s) = \sum_{1 \le m_1 < \dots < m_r < m} \frac{1}{m_1^{l_1} \cdots m_r^{l_r} m^s}$$

defined for positive integers l_1, \ldots, l_r , the analytic continuation of which has been given in [4] (the analytic continuation of a more general multi-variable multiple zeta function is established in [1]). This answers to the question posed in §5 of [4]. As a result, the function $\eta(k_1, \ldots, k_r; s)$ can also be written by the multiple zeta functions of the type above. We then give a formula for values at positive integers of $\xi(k_1, \ldots, k_r; s)$, and hence of $\eta(k_1, \ldots, k_r; s)$, in terms of the 'shuffle regularized values' of multiple zeta values, and thereby derive some consequences on the values of $\eta_k(s)$.

Let $\mathbf{k} = (k_1, \dots, k_r) \in \mathbb{Z}_{\geq 1}^r$ be an index set. Recall that \mathbf{k} is said to be admissible if the last entry k_r is greater than 1, the weight of \mathbf{k} is the sum $k_1 + \dots + k_r$, and the depth is the length r of the index. For two indices \mathbf{k} and \mathbf{k}' of the same weight, we say \mathbf{k}' refines \mathbf{k} , denoted $\mathbf{k} \leq \mathbf{k}'$, if \mathbf{k} is obtained from \mathbf{k}' by replacing some commas by +'s. For example, $(5) = (2+3) \leq (2,3), (2,3) = (1+1,2+1) \leq (1,1,2,1),$ etc. The standard expression of a multiple zeta-star value as a sum of multiple zeta values is written as

$$\zeta^{\star}(\mathbf{k}) = \sum_{\substack{\mathbf{k}' \leq \mathbf{k} \\ \text{admissible}}} \zeta(\mathbf{k}'),$$

where the sum on the right runs over the admissible indices \mathbf{k}' such that \mathbf{k} refines \mathbf{k}' .

The following formula is known as the Landen connection formula for the multiple polylogarithm ([26, Proposition 9]).

Lemma 3.1. For any index k of depth r, we have

(3.2)
$$\operatorname{Li}_{\mathbf{k}}\left(\frac{z}{z-1}\right) = (-1)^r \sum_{\mathbf{k} \prec \mathbf{k}'} \operatorname{Li}_{\mathbf{k}'}(z).$$

We can prove this by induction on weight and by using (2.3), see [26].

By using this and noting $z/(z-1) = 1 - e^t$ (resp. $1 - e^{-t}$) if $z = 1 - e^{-t}$ (resp. $1 - e^t$), we immediately obtain the following proposition.

Proposition 3.2. Let \mathbf{k} be any index set and r its depth. We have the relations

(3.3)
$$\eta(\mathbf{k}; s) = (-1)^{r-1} \sum_{\mathbf{k} \prec \mathbf{k}'} \xi(\mathbf{k}'; s)$$

and

(3.4)
$$\xi(\mathbf{k};s) = (-1)^{r-1} \sum_{\mathbf{k} \prec \mathbf{k}'} \eta(\mathbf{k}';s).$$

Corollary 3.3. Let k be a positive integer. Then we have

(3.5)
$$\eta_k(s) = \sum_{\mathbf{k}: weight \ k} \xi(\mathbf{k}; s)$$

and

(3.6)
$$\xi_k(s) = \sum_{\mathbf{k}: weight \ k} \eta(\mathbf{k}; s),$$

where the sums run over all indices of weight k. Here we have written $\xi_k(s)$ for $\xi(k;s)$.

Proof. The index (k) is of depth 1 and all indices of weight k (admissible or non-admissible) refine (k).

We mention here that, also by taking $\mathbf{k} = (k)$ in Lemma 3.1 and setting $z = 1 - e^t$ or $1 - e^{-t}$, one immediately obtains a kind of sum formulas for multi-poly-Bernoulli numbers as follows (compare with similar formulas in [17, Theorem 3.1]).

Corollary 3.4. For $k \ge 1$ and $m \ge 0$, we have

(3.7)
$$B_m^{(k)} = (-1)^m \sum_{\substack{k_1 + \dots + k_r = k \\ k_i, r > 1}} C_m^{(k_1, \dots, k_r)}$$

and

(3.8)
$$C_m^{(k)} = (-1)^m \sum_{\substack{k_1 + \dots + k_r = k \\ k_i, r > 1}} B_m^{(k_1, \dots, k_r)}.$$

Next, we prove an Euler-type connection formula for the multiple polylogarithm. If an index \mathbf{k} is of weight $|\mathbf{k}|$, we also say the multiple zeta value $\zeta(\mathbf{k})$ is of weight $|\mathbf{k}|$.

Lemma 3.5. Let k be any index. Then we have

(3.9)
$$\operatorname{Li}_{\mathbf{k}}(1-z) = \sum_{\mathbf{k}', j \geq 0} c_{\mathbf{k}}(\mathbf{k}'; j) \operatorname{Li}_{\underbrace{1, \dots, 1}_{j}} (1-z) \operatorname{Li}_{\mathbf{k}'}(z),$$

where the sum on the right runs over indices \mathbf{k}' and integers $j \geq 0$ that satisfy $|\mathbf{k}'| + j \leq |\mathbf{k}|$, and $c_{\mathbf{k}}(\mathbf{k}';j)$ is a \mathbb{Q} -linear combination of multiple zeta values of weight $|\mathbf{k}| - |\mathbf{k}'| - j$. We understand $\mathrm{Li}_{\emptyset}(z) = 1$ and $|\emptyset| = 0$ for the empty index \emptyset , and the constant 1 is regarded as a multiple zeta value of weight 0.

Proof. We proceed by induction on the weight of \mathbf{k} . When $\mathbf{k} = (1)$, the trivial identity $\text{Li}_1(1-z) = \text{Li}_1(1-z)$ is the one asserted. Suppose the weight $|\mathbf{k}|$ of \mathbf{k} is greater than 1 and assume the statement holds for any index of weight less than $|\mathbf{k}|$. For $\mathbf{k} = (k_1, \dots, k_r)$, set $\mathbf{k}_- = (k_1, \dots, k_{r-1}, k_r - 1)$ and $\mathbf{k}_+ = (k_1, \dots, k_{r-1}, k_r + 1)$.

First assume that k is admissible. Then, by (2.3) and induction hypothesis, we have

$$\frac{d}{dz}\mathrm{Li}_{\mathbf{k}}(1-z) = -\frac{\mathrm{Li}_{\mathbf{k}_{-}}(1-z)}{1-z} = -\frac{1}{1-z}\sum_{\mathbf{l},j\geq 0} c_{\mathbf{k}_{-}}(\mathbf{l};j)\mathrm{Li}_{\underbrace{\mathbf{l},\ldots,\mathbf{l}}_{j}}(1-z)\mathrm{Li}_{\mathbf{l}}(z),$$

the right-hand side being of a desired form. Here, again by (2.3), we see that

$$\frac{1}{1-z}\operatorname{Li}_{\underbrace{1,\ldots,1}_{j}}(1-z)\operatorname{Li}_{\mathbf{l}}(z) = \frac{d}{dz}\left(\sum_{i=0}^{j}\operatorname{Li}_{\underbrace{1,\ldots,1}_{j-i}}(1-z)\operatorname{Li}_{\mathbf{l},1+i}(z)\right).$$

We therefore conclude

$$\text{Li}_{\mathbf{k}}(1-z) = -\sum_{\mathbf{l},j\geq 0} c_{\mathbf{k}_{-}}(\mathbf{l};j) \sum_{i=0}^{j} \text{Li}_{\underbrace{1,\ldots,1}_{i-i}} (1-z) \text{Li}_{\mathbf{l},1+i}(z) + C$$

with some constant C. Since $\lim_{z\to 0} \operatorname{Li}_{\underbrace{1,\ldots,1}_{j-i}} (1-z) \operatorname{Li}_{1,1+i}(z) = 0$, we find $C = \zeta(\mathbf{k})$ by setting

 $z \rightarrow 0,$ and obtain the desired expression for $\mathrm{Li}_{\mathbf{k}}(1-z).$

When \mathbf{k} is not necessarily admissible, write $\mathbf{k} = (\mathbf{k}_0, \underbrace{1, \dots, 1}_q)$ with an admissible \mathbf{k}_0 and

 $q \ge 0$. We prove the identity by induction on q. The case q = 0 (**k** is admissible) is already done. Suppose $q \ge 1$ and assume the claim is true for smaller q. Then by assumption we have the expression

$$\operatorname{Li}_{\mathbf{k}_0,\underbrace{1,\ldots,1}_{q-1}}(1-z) = \sum_{\mathbf{m},j\geq 0} c_{\mathbf{k}'}(\mathbf{m};j) \operatorname{Li}_{\underbrace{1,\ldots,1}_{j}}(1-z) \operatorname{Li}_{\mathbf{m}}(z),$$

where we have put $\mathbf{k}' = (\mathbf{k}_0, \underbrace{1, \dots, 1}_{q-1})$. We multiply $\mathrm{Li}_1(1-z)$ on both sides. Then, by the shuffle

product, the left-hand side becomes the sum of the form

$$q \operatorname{Li}_{\mathbf{k}}(1-z) + \sum_{\mathbf{k}'_0: \text{admissible}} \operatorname{Li}_{\mathbf{k}'_0,\underbrace{1,\ldots,1}_{q-1}} (1-z),$$

and each term in the sum is written in the claimed form by induction hypothesis. On the other hand, the right-hand side becomes also of the form desired because

$$\operatorname{Li}_1(1-z)\operatorname{Li}_{\underbrace{1,\ldots,1}_{j}}(1-z)=(j+1)\operatorname{Li}_{\underbrace{1,\ldots,1}_{j+1}}(1-z).$$

Hence $\text{Li}_{\mathbf{k}}(1-z)$ is of the form as claimed.

With the lemma, we are now able to establish the following (see [4, §5, Problem (i)]).

Theorem 3.6. Let \mathbf{k} be any index set. The function $\xi(\mathbf{k}; s)$ can be written in terms of multiple zeta functions as

$$\xi(\mathbf{k};s) = \sum_{\mathbf{k}',j>0} c_{\mathbf{k}}(\mathbf{k}';j) \binom{s+j-1}{j} \zeta(\mathbf{k}';s+j).$$

Here, the sum is over indices \mathbf{k}' and integers $j \geq 0$ satisfying $|\mathbf{k}'| + j \leq |\mathbf{k}|$, and $c_{\mathbf{k}}(\mathbf{k}';j)$ is a \mathbb{Q} -linear combination of multiple zeta values of weight $|\mathbf{k}| - |\mathbf{k}'| - j$. The index \mathbf{k}' may be \emptyset and for this we set $\zeta(\emptyset; s + j) = \zeta(s + j)$.

Proof. By setting $z = e^{-t}$ in the lemma and using

(3.10)
$$\operatorname{Li}_{\underbrace{1,\dots,1}}(z) = \frac{(-\log(1-z))^j}{j!},$$

we have

$$\operatorname{Li}_{\mathbf{k}}(1 - e^{-t}) = \sum_{\mathbf{k}', j > 0} c_{\mathbf{k}}(\mathbf{k}'; j) \frac{t^{j}}{j!} \operatorname{Li}_{\mathbf{k}'}(e^{-t}).$$

Substituting this into the definition (1.2) of $\xi(\mathbf{k};s)$ and using the formula ([4, Proposition 2, (i)])

$$\zeta(\mathbf{k};s) = \frac{1}{\Gamma(s)} \int_0^\infty \frac{t^{s-1}}{e^t - 1} \mathrm{Li}_{\mathbf{k}}(e^{-t}) dt,$$

we immediately obtain the theorem.

Remark 3.7. This theorem generalizes [4, Theorem 8], where the corresponding formula for $\text{Li}_{\underbrace{1,\ldots,1},k}(1-z)$ is

$$\operatorname{Li}_{\underbrace{1,\dots,1}_{r-1},k}(1-z) = (-1)^{k-1} \sum_{\substack{j_1+\dots+j_k=r+k\\\forall j_i \ge 1}} \operatorname{Li}_{\underbrace{1,\dots,1}_{j_k-1}}(1-z) \operatorname{Li}_{j_1,\dots,j_{k-1}}(z) + \sum_{j=0}^{k-2} (-1)^j \zeta(\underbrace{1,\dots,1}_{r-1},k-j) \operatorname{Li}_{\underbrace{1,\dots,1}_{j}}(z).$$

As pointed out by Shu Oi, one can deduce Lemma 3.5 by induction using [27, Prop. 5]. However, to describe the right-hand side of the lemma explicitly is a different problem and neither proof gives such a formula in general. See also [25] for a related topic.

Example 3.8. Apart from the trivial case (1, ..., 1), examples of the identity in Lemma 3.5 up to weight 4 are:

$$\begin{array}{rcl} \operatorname{Li}_2(1-z) & = & -\operatorname{Li}_2(z) - \operatorname{Li}_1(1-z)\operatorname{Li}_1(z) + \zeta(2), \\ \operatorname{Li}_3(1-z) & = & \operatorname{Li}_{1,2}(z) + \operatorname{Li}_{2,1}(z) + \operatorname{Li}_1(1-z)\operatorname{Li}_{1,1}(z) - \zeta(2)\operatorname{Li}_1(z) + \zeta(3), \\ \operatorname{Li}_{1,2}(1-z) & = & -\operatorname{Li}_3(z) - \operatorname{Li}_1(1-z)\operatorname{Li}_2(z) - \operatorname{Li}_{1,1}(1-z)\operatorname{Li}_1(z) + \zeta(3), \\ \operatorname{Li}_{2,1}(1-z) & = & 2\operatorname{Li}_3(z) + \operatorname{Li}_1(1-z)\operatorname{Li}_2(z) + \zeta(2)\operatorname{Li}_1(1-z) - 2\zeta(3), \\ \operatorname{Li}_4(1-z) & = & -\operatorname{Li}_{1,1,2}(z) - \operatorname{Li}_{1,2,1}(z) - \operatorname{Li}_{2,1,1}(z) - \operatorname{Li}_1(1-z)\operatorname{Li}_{1,1,1}(z) \\ & & + \zeta(2)\operatorname{Li}_{1,1}(z) - \zeta(3)\operatorname{Li}_1(z) + \zeta(4), \end{array}$$

$$\begin{array}{rcl} \operatorname{Li}_{1,3}(1-z) & = & \operatorname{Li}_{1,3}(z) + \operatorname{Li}_{2,2}(z) + \operatorname{Li}_{3,1}(z) + \operatorname{Li}_{1}(1-z)\operatorname{Li}_{1,2}(z) + \operatorname{Li}_{1}(1-z)\operatorname{Li}_{2,1}(z) \\ & & & + \operatorname{Li}_{1,1}(1-z)\operatorname{Li}_{1,1}(z) - \zeta(3)\operatorname{Li}_{1}(z) + \frac{1}{4}\zeta(4), \\ \operatorname{Li}_{2,2}(1-z) & = & -\operatorname{Li}_{2,2}(z) - 2\operatorname{Li}_{3,1}(z) - \operatorname{Li}_{1}(1-z)\operatorname{Li}_{2,1}(z) - \zeta(2)\operatorname{Li}_{1}(1-z)\operatorname{Li}_{1}(z) \\ & & -\zeta(2)\operatorname{Li}_{2}(z) + 2\zeta(3)\operatorname{Li}_{1}(z) + \frac{3}{4}\zeta(4), \\ \operatorname{Li}_{3,1}(1-z) & = & -2\operatorname{Li}_{1,3}(z) - \operatorname{Li}_{2,2}(z) - \operatorname{Li}_{1}(1-z)\operatorname{Li}_{1,2}(z) + \zeta(2)\operatorname{Li}_{2}(z) \\ & & & +\zeta(3)\operatorname{Li}_{1}(1-z) - \frac{5}{4}\zeta(4), \\ \operatorname{Li}_{1,1,2}(1-z) & = & -\operatorname{Li}_{4}(z) - \operatorname{Li}_{1}(1-z)\operatorname{Li}_{3}(z) - \operatorname{Li}_{1,1}(1-z)\operatorname{Li}_{2}(z) \\ & & -\operatorname{Li}_{1,1,1}(1-z)\operatorname{Li}_{1}(z) + \zeta(4), \\ \operatorname{Li}_{1,2,1}(1-z) & = & 3\operatorname{Li}_{4}(z) + 2\operatorname{Li}_{1}(1-z)\operatorname{Li}_{3}(z) + \operatorname{Li}_{1,1}(1-z)\operatorname{Li}_{2}(z) + \zeta(3)\operatorname{Li}_{1}(1-z) \\ & & -3\zeta(4), \\ \operatorname{Li}_{2,1,1}(1-z) & = & -3\operatorname{Li}_{4}(z) - \operatorname{Li}_{1}(1-z)\operatorname{Li}_{3}(z) + \zeta(2)\operatorname{Li}_{1,1}(1-z) - 2\zeta(3)\operatorname{Li}_{1}(1-z) \\ & & +3\zeta(4) \end{array}$$

Accordingly, we have

$$\begin{array}{rcl} \xi(2;s) & = & -\zeta(2;s) - s\zeta(1;s+1) + \zeta(2)\zeta(s), \\ \xi(3;s) & = & \zeta(1,2;s) + \zeta(2,1;s) + s\zeta(1,1;s+1) - \zeta(2)\zeta(1;s) + \zeta(3)\zeta(s), \\ \xi(1,2;s) & = & -\zeta(3;s) - s\zeta(2;s+1) - \frac{s(s+1)}{2}\zeta(1;s+2) + \zeta(3)\zeta(s), \\ \xi(2,1;s) & = & 2\zeta(3;s) + s\zeta(2;s+1) + \zeta(2)s\zeta(s+1) - 2\zeta(3)\zeta(s), \\ \xi(4;s) & = & -\zeta(1,1,2;s) - \zeta(1,2,1;s) - \zeta(2,1,1;s) - s\zeta(1,1,1;s+1) \\ & & + \zeta(2)\zeta(1,1;s) - \zeta(3)\zeta(1;s) + \zeta(4)\zeta(s), \\ \xi(1,3;s) & = & \zeta(1,3;s) + \zeta(2,2;s) + \zeta(3,1;s) + s\zeta(1,2;s+1) + s\zeta(2,1;s+1) \\ & & + \frac{s(s+1)}{2}\zeta(1,1;s+2) - \zeta(3)\zeta(1;s) + \frac{1}{4}\zeta(4)\zeta(s), \\ \xi(2,2;s) & = & -\zeta(2,2;s) - 2\zeta(3,1;s) - s\zeta(2,1;s+1) - \zeta(2)s\zeta(1;s+1) \\ & & -\zeta(2)\zeta(2;s) + 2\zeta(3)\zeta(1;s) + \frac{3}{4}\zeta(4)\zeta(s), \\ \xi(3,1;s) & = & -2\zeta(1,3;s) - \zeta(2,2;s) - s\zeta(1,2;s+1) + \zeta(2)\zeta(2;s) \\ & & + \zeta(3)s\zeta(s+1) - \frac{5}{4}\zeta(4)\zeta(s), \\ \xi(1,1,2;s) & = & -\zeta(4;s) - s\zeta(3;s+1) - \frac{s(s+1)}{2}\zeta(2;s+2) \\ & & -\frac{s(s+1)(s+2)}{6}\zeta(1;s+3) + \zeta(4)\zeta(s), \\ \xi(1,2,1;s) & = & 3\zeta(4;s) + 2s\zeta(3;s+1) + \frac{s(s+1)}{2}\zeta(2;s+2) + \zeta(3)s\zeta(s+1) \\ & & -3\zeta(4)\zeta(s), \\ \xi(2,1,1;s) & = & -3\zeta(4;s) - s\zeta(3;s+1) + \zeta(2)\frac{s(s+1)}{2}\zeta(s+2) - 2\zeta(3)s\zeta(s+1) \\ & + 3\zeta(4)\zeta(s). \end{array}$$

From these and (3.5) of Corollary 3.3, we have for instance

$$\eta_2(s) = \xi(2;s) + \xi(1,1;s)$$

$$= -\zeta(2;s) - s\zeta(1;s+1) + \zeta(2)\zeta(s) + \frac{s(s+1)}{2}\zeta(s+2),$$

$$\eta_3(s) = \xi(3;s) + \xi(1,2;s) + \xi(2,1;s) + \xi(1,1,1;s)$$

$$= \zeta(3;s) + \zeta(1,2;s) + \zeta(2,1;s) + s\zeta(1,1;s+1) - \frac{s(s+1)}{2}\zeta(1;s+2)$$

$$-\zeta(2)\zeta(1;s) + \zeta(2)s\zeta(s+1) + \frac{s(s+1)(s+2)}{6}\zeta(s+3),$$

$$\eta_4(s) = \xi(4;s) + \xi(1,3;s) + \xi(2,2;s) + \xi(3,1;s) + \xi(1,1,2;s) + \xi(1,2,1;s)$$

$$+ \xi(2,1,1;s) + \xi(1,1,1,1;s)$$

$$= -\zeta(4;s) - \zeta(1,3;s) - \zeta(2,2;s) - \zeta(3,1;s) - \zeta(1,1,2;s) - \zeta(1,2,1;s)$$

$$-\zeta(2,1,1;s) - s\zeta(1,1,1;s+1) + \zeta(2)\zeta(1,1;s) + \frac{s(s+1)}{2}\zeta(1,1;s+2)$$

$$-\zeta(2)s\zeta(1;s+1) + \zeta(2)\frac{s(s+1)}{2}\zeta(s+2) - \frac{s(s+1)(s+2)}{6}\zeta(1;s+3)$$

$$+ \frac{7}{4}\zeta(4)\zeta(s) + \frac{s(s+1)(s+2)(s+3)}{24}\zeta(s+4).$$

Before closing this section, we present a curious observation. Recall the formula

$$\xi_k(m) = \zeta^*(\underbrace{1,\ldots,1}_{m-1},k+1)$$

discovered by Ohno [24]. Comparing this with the two formulas (2.11) and [4, Corollary 10], one may expect

$$\eta_k(m) \stackrel{?}{=} \zeta(\underbrace{1,\ldots,1}_{m-1},k+1).$$

This is not true in fact. However, we found experimentally the identities

and

(3.12)
$$\sum_{j=1}^{k-1} (-1)^{j-1} \eta_{k-j}(j) = \begin{cases} 2(1-2^{1-k})\zeta(k) & (k: \text{ even}), \\ 0 & (k: \text{ odd}). \end{cases}$$

These are respectively analogous to the duality relation

$$\zeta(\underbrace{1,\ldots,1}_{m-1},k+1) = \zeta(\underbrace{1,\ldots,1}_{k-1},m+1)$$

and the relation

$$\sum_{j=1}^{k-1} (-1)^{j-1} \zeta(\underbrace{1, \dots, 1}_{j-1}, k-j+1) = \begin{cases} 2(1-2^{1-k})\zeta(k) & (k: \text{ even}), \\ 0 & (k: \text{ odd}), \end{cases}$$

which is a special case of the Le-Murakami relation [23] (or one can derive this from the well-known generating series identity [2], [11]

$$1 - \sum_{k>j\geq 1} \zeta(\underbrace{1,\ldots,1}_{j-1}, k-j+1) X^{k-j} Y^j = \frac{\Gamma(1-X)\Gamma(1-Y)}{\Gamma(1-X-Y)}$$

by setting Y = -X and using the reflection formula for the gamma function.)

We are still not able to prove (3.11)*, but could prove (3.12) by using the following general

^{*}Quite recently, Shuji Yamamoto communicated to the authors that he found a proof.

formula for the value $\xi(\mathbf{k}; m)$ and the relation (3.3) in Proposition 3.2. We shall discuss this and other aspects of 'height one' multiple zeta values in more detail in a subsequent paper [22].

Proposition 3.9. Let **k** be any index and $m \ge 1$ an integer. Then we have

(3.13)
$$\xi(\mathbf{k}; m) = (-1)^{m-1} \zeta^{\text{III}}(\mathbf{k}_+, \underbrace{1, \dots, 1}_{m-1}),$$

where ζ^{III} stands for the 'shuffle regularized' value, which is the constant term of the shuffle regularized polynomial defined in [19].

Proof. By making the change of variable $x = 1 - e^{-t}$ in the definition (1.2), we have

$$\xi(\mathbf{k}; s) = \frac{1}{\Gamma(s)} \int_0^1 \left(-\log(1-x)\right)^{s-1} \mathrm{Li}_{\mathbf{k}}(x) \, \frac{dx}{x}.$$

Put s = m and use (3.10) to obtain

$$\xi(\mathbf{k}; m) = \int_0^1 \operatorname{Li}_{\underbrace{1, \dots, 1}_{m-1}}(x) \operatorname{Li}_{\mathbf{k}}(x) \frac{dx}{x}.$$

The regularization formula [19, Eq. (5.2)], together with the shuffle product of $\underset{m-1}{\text{Li}_{1,...,1}}(x)\underset{m-1}{\text{Li}_{\mathbf{k}}}(x)$, immediately gives (3.13).

By using (3.13) and (3.5), we can write $\eta_k(m)$ in terms of shuffle regularized values. The following expression seems to follow from that formula by taking the dual, but we have not yet worked it out in detail.

$$\eta_k(m) \stackrel{?}{=} \binom{m+k}{k} \zeta(m+k) - \sum_{\substack{2 \le r \le k+1 \\ j_1 + \dots + j_r = m+k-r-1}} \binom{j_1 + \dots + j_{r-1}}{k-r+1} \zeta(j_1 + 1, \dots, j_{r-1} + 1, j_r + 2).$$

4. The function $\eta(k_1,\ldots,k_r;s)$ for non-positive indices

In this section, as in the case of positive indices, we construct η -functions with non-positive indices. It is known that $\text{Li}_{-k}(z)$ can be expressed as

$$\text{Li}_{-k}(z) = \frac{P(z;k)}{(1-z)^k}$$

for $k \in \mathbb{Z}_{\geq 0}$, where $P(x; k) \in \mathbb{Z}[x]$ is a monic polynomial satisfying

$$\deg P(x;k) = \begin{cases} 1 & (k=0) \\ k & (k \ge 1), \end{cases}$$
$$x \mid P(x;k)$$

(see, for example, Shimura [29, Equations (2.17), (4.2) and (4.6)]; Note that the above P(x;k) coincides with $xP_{k+1}(x)$ in [29]). We first extend this fact to multiple polylogarithms with non-positive indices as follows.

Lemma 4.1. For $k_1, \ldots, k_r \in \mathbb{Z}_{\geq 0}$, there exists a polynomial $P(x; k_1, \ldots, k_r) \in \mathbb{Z}[x]$ such that

(4.1)
$$\operatorname{Li}_{-k_1,\dots,-k_r}(z) = \frac{P(z; k_1,\dots,k_r)}{(1-z)^{k_1+\dots+k_r+r}}$$

(4.2)
$$\deg P(x; k_1, \dots, k_r) = \begin{cases} r & (k_1 = \dots = k_r = 0) \\ k_1 + \dots + k_r + r - 1 & (\text{otherwise}), \end{cases}$$

(4.3)
$$x^r \mid P(x; k_1, \dots, k_r).$$

More explicitly, $P(x; \underbrace{0, 0, \dots, 0}_{r}) = x^{r}$.

Proof. We prove this lemma by the double induction on $r \ge 1$ and $K = k_1 + \dots + k_r \ge 0$. The case r = 1 is as mentioned above. For $r \ge 2$, we assume the case of r - 1 holds and consider the case of r. When $K = k_1 + \dots + k_r = 0$, namely $k_1 = \dots = k_r = 0$, we have

$$\operatorname{Li}_{0,\dots,0}(z) = \sum_{m_1 < \dots < m_r} x^{m_r} = \sum_{m_1 < \dots < m_{r-1}} \sum_{m_r = m_{r-1} + 1}^{\infty} z^{m_r}$$
$$= \frac{z}{1 - z} \sum_{m_1 < \dots < m_{r-1}} z^{m_{r-1}} = \dots = \frac{z^r}{(1 - z)^r},$$

which implies (4.1)–(4.3) hold, and also $P(x; 0, ..., 0) = x^r$. Hence we assume the case $K = k_1 + \cdots + k_r - 1$ holds and consider the case $K = k_1 + \cdots + k_r \ge 1$. We consider the two cases $k_r = 0$ and $k_r \ge 1$ separately. First we assume $k_r = 0$. Then, by induction hypothesis, we have

$$\operatorname{Li}_{-k_1,\dots,-k_{r-1},0}(z) = \sum_{m_1 < \dots < m_{r-1}} m_1^{k_1} \cdots m_{r-1}^{k_{r-1}} \sum_{m_r = m_{r-1}+1}^{\infty} z^{m_r}$$

$$= \frac{z}{1-z} \sum_{m_1 < \dots < m_{r-1}} m_1^{k_1} \cdots m_{r-1}^{k_{r-1}} z^{m_{r-1}}$$

$$= \frac{z}{1-z} \frac{P(z : k_1, \dots, k_{r-1})}{(1-z)^{k_1 + \dots + k_{r-1} + r - 1}}.$$

Let $P(z; k_1, \dots, k_{r-1}, 0) = zP(z; k_1, \dots, k_{r-1})$. Then (4.1)–(4.3) hold.

Next we assume $k_r \geq 1$. Then, using the same formula as in (2.3) and the induction hypothesis, we have

$$\operatorname{Li}_{-k_1,\dots,-k_{r-1},-k_r}(z) = z \frac{d}{dz} \operatorname{Li}_{-k_1,\dots,-k_r+1}(z)
= z \frac{d}{dz} \left(\frac{P(z:k_1,\dots,k_r-1)}{(1-z)^{k_1+\dots+k_r-1+r}} \right)
= \frac{z \left\{ P'(z:k_1,\dots,k_r-1)(1-z) + (k_1+\dots+k_r-1+r)P(z;k_1,\dots,k_r-1) \right\}}{(1-z)^{k_1+\dots+k_r+r}}.$$

If $k_1 = \cdots = k_{r-1} = 0$ and $k_r = 1$, then the numerator, that is, $P(0, \ldots, 0, -1)$ equals rz^r , using the above results. If not, the degree of the numerator equals $k_1 + \cdots + k_r + r - 1$ by induction hypothesis. The both cases satisfy (4.1)–(4.3). This completes the proof of the lemma.

Remark 4.2. In the case $r \geq 2$, $P(x; k_1, ..., k_r)$ is not necessarily a monic polynomial. For example, we have $\text{Li}_{0,-1}(z) = 2z^2/(1-z)^3$, so $P(x;0,1) = 2x^2$.

We obtain from (4.1) and (4.2) that

(4.4)
$$\operatorname{Li}_{-k_1,\dots,-k_r}(1-e^t) = \frac{P(1-e^t; k_1,\dots,k_r)}{e^{(k_1+\dots+k_r+r)t}} = \begin{cases} O(1) & (k_1=\dots=k_r=0) \\ O(e^{-t}) & (\text{otherwise}) \end{cases}$$

as $t \to \infty$, and from (4.3) that

(4.5)
$$\operatorname{Li}_{-k_1,\dots,-k_r}(1-e^t) = O(t^r) \quad (t \to 0).$$

Therefore we can define the following.

Definition 4.3. For $k_1, \ldots, k_r \in \mathbb{Z}_{>0}$, define

(4.6)
$$\eta(-k_1, \dots, -k_r; s) = \frac{1}{\Gamma(s)} \int_0^\infty t^{s-1} \frac{\operatorname{Li}_{-k_1, \dots, -k_r} (1 - e^t)}{1 - e^t} dt$$

for $s \in \mathbb{C}$ with Re(s) > 1 - r. In the case r = 1, denote $\eta(-k; s)$ by $\eta_{-k}(s)$.

We see that the integral on the right-hand side of (4.6) is absolutely convergent for Re(s) > 1 - r. Hence $\eta(-k_1, \ldots, -k_r; s)$ is holomorphic for Re(s) > 1 - r. By the same method as in the proof of Theorem 2.3 for $\eta(k_1, \ldots, k_r; s)$, we can similarly obtain the following.

Theorem 4.4. For $k_1, \ldots, k_r \in \mathbb{Z}_{\geq 0}$, $\eta(-k_1, \ldots, -k_r; s)$ can be analytically continued to an entire function on the whole complex plane, and satisfies

(4.7)
$$\eta(-k_1, \dots, -k_r; -m) = B_m^{(-k_1, \dots, -k_r)} \quad (m \in \mathbb{Z}_{\geq 0}).$$

In particular, $\eta_{-k}(-m) = B_m^{(-k)} \ (k \in \mathbb{Z}_{\geq 0}, \ m \in \mathbb{Z}_{\geq 0}).$

It should be noted that $\xi(-k_1, \ldots, -k_r; s)$ cannot be defined by replacing $\{k_j\}$ by $\{-k_j\}$ in (1.2). In fact, even if r = 1 and k = 0 in (1.2), we see that

$$\xi_0(s) = \frac{1}{\Gamma(s)} \int_0^\infty t^{s-1} \frac{\text{Li}_0(1 - e^{-t})}{e^t - 1} dt = \frac{1}{\Gamma(s)} \int_0^\infty t^{s-1} dt,$$

which is not convergent for any $s \in \mathbb{C}$. Therefore we modify the definition (1.2) as follows.

Definition 4.5. For $k_1, \ldots, k_r \in \mathbb{Z}_{\geq 0}$ with $(k_1, \ldots, k_r) \neq (0, \ldots, 0)$, define

(4.8)
$$\widetilde{\xi}(-k_1, \dots, -k_r; s) = \frac{1}{\Gamma(s)} \int_0^\infty t^{s-1} \frac{\operatorname{Li}_{-k_1, \dots, -k_r} (1 - e^t)}{e^{-t} - 1} dt$$

for $s \in \mathbb{C}$ with Re(s) > 1 - r. In the case r = 1, denote $\widetilde{\xi}(-k; s)$ by $\widetilde{\xi}_{-k}(s)$ for $k \geq 1$.

We see from (4.4) and (4.5) that (4.8) is well-defined. Also it is noted that $\widetilde{\xi}(k_1, \dots, k_r; s)$ cannot be defined by replacing $\{-k_j\}$ by $\{k_j\}$ in (4.8) for $(k_j) \in \mathbb{Z}_{>1}^r$.

In a way parallel to deriving Theorem 4.4, we can obtain the following.

Theorem 4.6. For $k_1, \ldots, k_r \in \mathbb{Z}_{\geq 0}$ with $(k_1, \ldots, k_r) \neq (0, \ldots, 0)$, $\widetilde{\xi}(-k_1, \ldots, -k_r; s)$ can be analytically continued to an entire function on the whole complex plane, and satisfies

(4.9)
$$\widetilde{\xi}(-k_1, \dots, -k_r; -m) = C_m^{(-k_1, \dots, -k_r)} \quad (m \in \mathbb{Z}_{\geq 0}).$$

In particular, $\widetilde{\xi}_{-k}(-m) = C_m^{(-k)} \ (k \in \mathbb{Z}_{\geq 1}, \ m \in \mathbb{Z}_{\geq 0}).$

Next we give certain duality formulas for $B_n^{(k_1,\ldots,k_r)}$ which is a generalization of (1.6). To state this, we define another type of multi-poly-Bernoulli numbers by

(4.10)
$$\sum_{a=0}^{r-1} (-1)^a \binom{r-1}{a} \sum_{l_1,\dots,l_r \ge 1} \frac{\prod_{j=1}^r \left(1 - e^{-\sum_{\nu=j}^r x_\nu}\right)^{l_j-1}}{(l_1 + \dots + l_r - a)^s}$$

$$= \sum_{m_1,\dots,m_r \ge 0} \mathfrak{B}_{m_1,\dots,m_r}^{(s)} \frac{x_1^{m_1} \cdots x_r^{m_r}}{m_1! \cdots m_r!}$$

for $s \in \mathbb{C}$. In the case r = 1, we see that $\mathfrak{B}_m^{(k)} = B_m^{(k)}$ for $k \in \mathbb{Z}$. Then we obtain the following result which is a kind of the duality formula. In fact, this coincides with (1.6) in the case r = 1.

Theorem 4.7. For $k_1, \ldots, k_r \in \mathbb{Z}_{>0}$,

(4.11)
$$\eta(-k_1, \dots, -k_r; s) = \mathfrak{B}_{k_1, \dots, k_r}^{(s)}.$$

Therefore, for $m \in \mathbb{Z}_{\geq 0}$,

$$(4.12) B_m^{(-k_1,\dots,-k_r)} = \mathfrak{B}_{k_1,\dots,k_r}^{(-m)}$$

Proof. We first prepare the following relation which will be proved in the next section (see Lemma 5.9):

(4.13)
$$\prod_{j=1}^{r} \frac{e^{\sum_{\nu=j}^{r} x_{\nu}} (1 - e^{t})}{1 - e^{\sum_{\nu=j}^{r} x_{\nu}} (1 - e^{t})} = \sum_{k_{1}, \dots, k_{r} > 0} \operatorname{Li}_{-k_{1}, \dots, -k_{r}} (1 - e^{t}) \frac{x_{1}^{k_{1}} \cdots x_{r}^{k_{r}}}{k_{1}! \cdots k_{r}!}$$

holds around the origin. Let

$$\mathfrak{F}(x_1, \dots, x_r; s) = \sum_{k_1, \dots, k_r > 0} \eta(-k_1, \dots, -k_r; s) \frac{x_1^{k_1} \cdots x_r^{k_r}}{k_1! \cdots k_r!}.$$

As a generalization of [18, Proposition 5], we have from (4.13) that

$$\mathcal{F}(x_1, \dots, x_r; s) = \frac{1}{\Gamma(s)} \int_0^\infty \frac{t^{s-1}}{1 - e^t} \prod_{j=1}^r \frac{e^{\sum_{\nu=j}^r x_{\nu}} (1 - e^t)}{1 - e^{\sum_{\nu=j}^r x_{\nu}} (1 - e^t)} dt
= \frac{1}{\Gamma(s)} \int_0^\infty t^{s-1} (1 - e^t)^{r-1} e^{-rt} \prod_{j=1}^r \frac{1}{1 - e^{-t} \left(1 - e^{-\sum_{\nu=j}^r x_{\nu}}\right)} dt
= \frac{1}{\Gamma(s)} \sum_{a=0}^{r-1} (-1)^a \binom{r-1}{a} \sum_{m_1, \dots, m_r \ge 0} \prod_{j=1}^r \left(1 - e^{-\sum_{\nu=j}^r x_{\nu}}\right)^{m_j}
\times \int_0^\infty t^{s-1} e^{(a-r)t} \prod_{j=1}^r e^{-m_j t} dt
= \sum_{a=0}^{r-1} (-1)^a \binom{r-1}{a} \sum_{m_1, \dots, m_r \ge 0} \frac{\prod_{j=1}^r \left(1 - e^{-\sum_{\nu=j}^r x_{\nu}}\right)^{m_j}}{(m_1 + \dots + m_r + r - a)^s}.$$

Therefore, by (4.10), we obtain (4.11). Further, setting s = -m in (4.11) and using (4.7), we obtain (4.12).

Remark 4.8. In the case r = 1, (4.11) implies $\eta_{-k}(s) = B_k^{(s)}$. Thus, using Theorem 4.4, we obtain the duality formula (1.6), which is also written as

$$(4.14) \eta_{-k}(-m) = \eta_{-m}(-k)$$

for $k, m \in \mathbb{Z}_{\geq 0}$. This is exactly contrasted with the positive index case (3.11). Furthermore, by the same method, we can show that $\widetilde{\xi}_{-k-1}(-m) = C_{k+1}^{(-m)}$ for $k, m \in \mathbb{Z}_{\geq 0}$. Hence, using Theorem 4.6 in the case r = 1, we obtain the duality formula (1.7).

Example 4.9. When r = 2, we can calculate directly from (4.10) that $\mathfrak{B}_{1,0}^{(s)} = 3^{-s} - 2^{-s}$. On the other hand, as mentioned in Lemma 4.1, we have $\text{Li}_{-1,0}(z) = z^2/(1-z)^3$. Hence the left-hand side of (1.10) equals

$$\frac{\operatorname{Li}_{-1,0}(1-e^{-t})}{1-e^{-t}} = \frac{1-e^{-t}}{e^{-3t}} = e^{3t} - e^{2t},$$

hence $B_m^{(-1,0)} = 3^m - 2^m$. Thus we can verify $B_m^{(-1,0)} = \mathfrak{B}_{1,0}^{(-m)}$.

5. Multi-indexed poly-Bernoulli numbers and duality formulas

In this section, we define multi-indexed poly-Bernoulli numbers (see Definition 5.1) and prove the duality formula for them, namely a multi-indexed version of (1.6) (see Theorem 5.4).

For this aim, we first recall multiple polylogarithms of *-type and of $\underline{\mathsf{w}}$ -type in several variables defined by

(5.1)
$$\operatorname{Li}_{s_1,\dots,s_r}^*(z_1,\dots,z_r) = \sum_{1 \le m_1 < \dots < m_r} \frac{z_1^{m_1} \cdots z_r^{m_r}}{m_1^{s_1} m_2^{s_2} \cdots m_r^{s_r}},$$

(5.2)
$$\operatorname{Li}_{s_{1},\dots,s_{r}}^{\mathbf{m}}(z_{1},\dots,z_{r}) = \sum_{1 \leq m_{1} < \dots < m_{r}} \frac{z_{1}^{m_{1}} z_{2}^{m_{2}-m_{1}} \cdots z_{r}^{m_{r}-m_{r-1}}}{m_{1}^{s_{1}} m_{2}^{s_{2}} \cdots m_{r}^{s_{r}}}$$
$$= \sum_{l_{1},\dots,l_{r}=1}^{\infty} \frac{z_{1}^{l_{1}} z_{2}^{l_{2}} \cdots z_{r}^{l_{r}}}{l_{1}^{s_{1}} (l_{1}+l_{2})^{s_{2}} \cdots (l_{1}+\dots+l_{r})^{s_{r}}}$$

for $s_1, \ldots, s_r \in \mathbb{C}$ and $z_1, \cdots, z_r \in \mathbb{C}$ with $|z_j| \leq 1$ $(1 \leq j \leq r)$ (see, for example, [13]). The symbols * and \mathbf{m} are derived from the harmonic product and the shuffle product in the theory of multiple zeta values. In fact, Arakawa and the first-named author defined the two types of multiple L-values $L^*(k_1, \ldots, k_r; f_1, \ldots, f_r)$ of *-type and $L^{\mathbf{m}}(k_1, \ldots, k_r; f_1, \ldots, f_r)$ of \mathbf{m} -type associated to periodic functions $\{f_j\}$ (see [5]), defined by replacing $\{z_j^m\}$ by $\{f_j(m)\}$ and setting $\{s_j\} = (k_j) \in \mathbb{Z}_{\geq 1}^r$ on the right-hand sides of (5.1) and (5.2) for $(k_1, \ldots, k_r) \in \mathbb{Z}_{\geq 1}^r$. Note that

(5.3)
$$\operatorname{Li}_{s_1,\dots,s_r}^*(z_1,\dots,z_r) = \operatorname{Li}_{s_1,\dots,s_r}^{\mathbf{m}}(\prod_{j=1}^r z_j, \prod_{j=2}^r z_j,\dots,z_{r-1}z_r,z_r).$$

Definition 5.1 (Multi-indexed poly-Bernoulli numbers). For $s_1, \ldots, s_r \in \mathbb{C}$ and $d \in \{1, 2, \ldots, r\}$, the multi-indexed poly-Bernoulli numbers $\{B_{m_1, \ldots, m_r}^{(s_1, s_2, \ldots, s_r), (d)}\}$ are defined by

(5.4)
$$F(x_1, \dots, x_r; s_1, \dots, s_r; d) = \frac{\operatorname{Li}_{s_1, \dots, s_r}^{\mathbf{u}} \left(1 - e^{-\sum_{\nu=1}^r x_{\nu}}, \dots, 1 - e^{-x_{r-1} - x_r}, 1 - e^{-x_r} \right)}{\prod_{j=1}^d \left(1 - e^{-\sum_{\nu=j}^r x_{\nu}} \right)}$$

$$\left(= \sum_{l_1,\dots,l_r=1}^{\infty} \frac{\prod_{j=1}^r \left(1 - e^{-\sum_{\nu=j}^r x_{\nu}}\right)^{l_j - \delta_j(d)}}{\prod_{j=1}^r \left(\sum_{\nu=1}^j l_{\nu}\right)^{s_j}} \right) \\
= \sum_{m_1,\dots,m_r=0}^{\infty} B_{m_1,\dots,m_r}^{(s_1,\dots,s_r),(d)} \frac{x_1^{m_1} \cdots x_r^{m_r}}{m_1! \cdots m_r!},$$

where $\delta_{i}(d) = 1 \ (j \leq d), = 0 \ (j > d).$

Remark 5.2. Note that $\text{Li}_{k_1,\ldots,k_r}^{\mathsf{u}}(z,\ldots,z) = \text{Li}_{k_1,\ldots,k_r}(z)$ defined by (1.9). Suppose $x_1 = \cdots = x_{r-1} = 0$ and $(s_j) = (k_j) \in \mathbb{Z}^r$ in (5.4). We immediately see that if d = 1 then

$$B_{0,\dots,0,m}^{(k_1,\dots,k_r),(1)} = B_m^{(k_1,\dots,k_r)} \qquad (m \in \mathbb{Z}_{\geq 0})$$

(see (1.6)), and if d = r then

$$B_{0,\dots,0,m}^{(k_1,\dots,k_r),(r)} = \mathbb{B}_m^{(k_1,\dots,k_r)} \qquad (m \in \mathbb{Z}_{\geq 0})$$

(see (1.8)).

Remark 5.3. Let

(5.5)
$$\Lambda_r = \{(x_1, \dots, x_r) \in \mathbb{C}^r \mid |1 - e^{-\sum_{\nu=j}^r x_{\nu}}| < 1 \ (1 \le j \le r)\}.$$

Then we can see that

$$\operatorname{Li}_{s_1,\dots,s_r}^{\mathsf{u}} \left(1 - e^{-\sum_{\nu=1}^r x_{\nu}}, \dots, 1 - e^{-x_{r-1} - x_r}, 1 - e^{-x_r} \right) \quad (s_1,\dots,s_r \in \mathbb{C})$$

is absolutely convergent for $(x_j) \in \Lambda_r$. Also $F(x_1, \dots, x_r; s_1, \dots, s_r; d)$ is absolutely convergent in the region $\Lambda_r \times \mathbb{C}^r$, so is holomorphic. Hence $B_{m_1, \dots, m_r}^{(s_1, \dots, s_r), (d)}$ is an entire function, because

$$B_{m_1,\dots,m_r}^{(s_1,\dots,s_r),(d)} = \left(\frac{\partial}{\partial x_1}\right)^{m_1} \cdots \left(\frac{\partial}{\partial x_r}\right)^{m_r} F(x_1,\dots,x_r;s_1,\dots,s_r;d)\Big|_{(x_1,\dots,x_r)=(0,\dots,0)}$$

is holomorphic for all $(s_1, \ldots, s_r) \in \mathbb{C}^r$.

In the preceding section, we gave a certain duality formula for $B_m^{(k_1,\ldots,k_r)}$ (see Theorem 4.7). By the similar method, we can prove certain duality formulas for $B_{m_1,\ldots,m_r}^{(k_1,\ldots,k_r),(d)}$, though they may be complicated. Hence, in the rest of this section, we will consider the case d=r. For emphasis, we denote $B_{m_1,\ldots,m_r}^{(s_1,\ldots,s_r),(r)}$ by $\mathbb{B}_{m_1,\ldots,m_r}^{(s_1,\ldots,s_r)}$. Note that $\delta_j(r)=1$ for any j. With this notation, we prove the following duality formulas.

Theorem 5.4. For $m_1, ..., m_r, k_1, ..., k_r \in \mathbb{Z}_{>0}$,

(5.6)
$$\mathbb{B}_{m_1,\dots,m_r}^{(-k_1,\dots,-k_r)} = \mathbb{B}_{k_1,\dots,k_r}^{(-m_1,\dots,-m_r)}.$$

Now we aim to prove this theorem. First we generalize Lemma 4.1 as follows.

Lemma 5.5. For $k_1, \ldots, k_r \in \mathbb{Z}_{\geq 0}$, there exists a polynomial $\widetilde{P}(x_1, \ldots, x_r; k_1, \ldots, k_r) \in \mathbb{Z}[x_1, \ldots, x_r]$ such that

(5.7)
$$\operatorname{Li}_{-k_1,\dots,-k_r}^*(z_1,\dots,z_r) = \frac{\widetilde{P}(\prod_{j=1}^r z_j, \prod_{j=2}^r z_j,\dots,z_{r-1}z_r, z_r; k_1,\dots,k_r)}{\prod_{j=1}^r \left(1 - \prod_{\nu=j}^r z_\nu\right)^{\sum_{\nu=j}^r k_\nu + 1}},$$

(5.8)
$$\deg_{x_j} \widetilde{P}(x_1, \dots, x_r; k_1, \dots, k_r) \le \sum_{\nu=j}^r k_{\nu} + 1,$$

(5.9)
$$(x_1 \cdots x_r) \mid \widetilde{P}(x_1, \dots, x_r; k_1, \dots, k_r).$$

Set $y_j = \prod_{\nu=j}^r z_{\nu}$ $(1 \le j \le r)$. Then (5.7) implies

(5.10)
$$\operatorname{Li}_{-k_1,\dots,-k_r}^{\mathbf{u}}(y_1,\dots,y_r) = \frac{\widetilde{P}(y_1,\dots,y_r;k_1,\dots,k_r)}{\prod_{j=1}^r (1-y_j)^{\sum_{\nu=j}^r k_{\nu}+1}}.$$

Proof. In order to prove this lemma, we have only to use the same method as in Lemma 4.1 by induction on r. Since the case of r=1 is proven, we consider the case of $r\geq 2$. Further, when $K=k_1+\cdots+k_r=0$, it is easy to have the assertion. Hence we think about a general case $K=k_1+\cdots+k_r(\geq 1)$. When $k_r=0$, we have

$$\operatorname{Li}_{-k_{1},\dots,-k_{r}}^{*}(z_{1},\dots,z_{r}) = \frac{z_{r}}{1-z_{r}} \operatorname{Li}_{-k_{1},\dots,-k_{r-1}}^{*}(z_{1},\dots,z_{r-2},z_{r-1}z_{r})$$

$$= \frac{z_{r}}{1-z_{r}} \frac{\widetilde{P}(\prod_{j=1}^{r} z_{j},\dots,z_{r-1}z_{r};k_{1},\dots,k_{r-1})}{\prod_{j=1}^{r-1} \left(1-\prod_{\nu=j}^{r} z_{j}\right)^{\sum_{\nu=j}^{r} k_{\nu}+1}}.$$

Therefore, setting $\widetilde{P}(x_1, \dots, x_r; k_1, \dots, k_{r-1}, 0) = x_r \widetilde{P}(x_1, \dots, x_{r-1}; k_1, \dots, k_{r-1})$, we can verify (5.7)–(5.9).

Next we consider the case $k_r \geq 1$. For $k \in \mathbb{Z}_{\geq 0}$, we inductively define a subset $\{c_{j,\nu}^{(k)}\}_{0 \leq j,\nu \leq k+1}$ of \mathbb{Z} by

(5.11)
$$\frac{d}{dz} \left(\sum_{m>l} m^k z^m \right) = \frac{1}{(1-z)^{k+2}} \sum_{j=0}^{k+1} \sum_{\nu=0}^{k+1} c_{j,\nu}^{(k)} l^{\nu} z^{l+j}.$$

In fact, by

$$\frac{d}{dz}\left(\sum_{m>l}z^m\right) = \frac{1}{(1-z)^2}\left(z^l + lz^l - lz^{l+1}\right),\,$$

and

$$\sum_{m>l} m^k z^m = z \frac{d}{dz} \left(\sum_{m>l} m^{k-1} z^m \right) \qquad (k \ge 1),$$

we can determine $\{c_{j,\nu}^{(k)}\}$ by (5.11). Using this notation, we have

$$\begin{split} & \operatorname{Li}_{-k_1, \dots, -k_r}^*(z_1, \dots, z_r) = z_r \frac{d}{dz_r} \operatorname{Li}_{-k_1, \dots, -k_r+1}^*(z_1, \dots, z_r) \\ &= z_r \sum_{m_1 < \dots < m_{r-1}} m_1^{k_1} \cdots m_{r-1}^{k_{r-1}} z_1^{m_1} \cdots z_{r-1}^{m_{r-1}} \frac{\sum_{j=0}^{k_r} \sum_{\nu=0}^{k_r} c_{j,\nu}^{(k_r-1)} m_{r-1}^{\nu} z_r^{m_{r-1}+j}}{(1 - z_r)^{k_r+1}} \\ &= \frac{1}{(1 - z_r)^{k_r+1}} \sum_{j=0}^{k_r} \sum_{\nu=0}^{k_r} c_{j,\nu}^{(k_r-1)} z_r^{j+1} \sum_{m_1 < \dots < m_{r-1}} m_1^{k_1} \cdots m_{r-1}^{k_{r-1}+\nu} z_1^{m_1} \cdots (z_{r-1} z_r)^{m_{r-1}}. \end{split}$$

By the induction hypothesis in the case r-1, this is equal to

$$\frac{1}{(1-z_r)^{k_r+1}} \sum_{j=0}^{k_r} \sum_{\nu=0}^{k_r} c_{j,\nu}^{(k_r-1)} z_r^{j+1} \frac{\widetilde{P}(\prod_{j=1}^{r-1} z_j, \dots, z_{r-1} z_r; k_1, \dots, k_{r-2}, k_{r-1} + \nu)}{\prod_{j=1}^{r-2} \left(1 - \prod_{\nu=j}^{r} z_j\right)^{\sum_{\nu=j}^{r} k_{\nu}+1} (1 - z_{r-1} z_r)^{k_{r-1}+\nu+1}}.$$

Therefore we set

$$\widetilde{P}(x_1, \dots, x_r; k_1, \dots, k_r) = \sum_{j=0}^{k_r} \sum_{\nu=0}^{k_r} c_{j,\nu}^{(k_r-1)} x_r^{j+1} (1 - x_{r-1})^{k_r-\nu} \widetilde{P}(x_1, \dots, x_{r-1}; k_1, \dots, k_{r-2}, k_{r-1} + \nu).$$

Then this satisfies (5.7)–(5.9). This completes the proof.

From this result, we can reach the following definition.

Definition 5.6. For $k_1, \ldots, k_r \in \mathbb{Z}_{>0}$, define

(5.12)
$$\eta(-k_1, \dots, -k_r; s_1, \dots, s_r) = \frac{1}{\prod_{j=1}^r \Gamma(s_j)} \int_0^\infty \dots \int_0^\infty \prod_{j=1}^r t_j^{s_j - 1} \times \frac{\operatorname{Li}_{-k_1, \dots, -k_r}^{\mathbf{u}} (1 - e^{\sum_{\nu=1}^r t_{\nu}}, \dots, 1 - e^{t_{r-1} + t_r}, 1 - e^{t_r})}{\prod_{j=1}^r (1 - e^{\sum_{\nu=j}^r t_{\nu}})} \prod_{j=1}^r dt_j$$

for $s_1, \ldots, s_r \in \mathbb{C}$ with $\text{Re}(s_j) > 0$ $(1 \le j \le r)$.

Lemma 5.5 ensures that the integral on the right-hand side of (5.12) is absolutely convergent for $\text{Re}(s_j) > 0$. By the same method as in the proof of Theorem 2.3 for $\eta(k_1, \ldots, k_r; s)$, we can similarly obtain the following.

Theorem 5.7. For $k_1, \ldots, k_r \in \mathbb{Z}_{\geq 0}$, $\eta(-k_1, \ldots, -k_r; s_1, \ldots, s_r)$ can be analytically continued to an entire function on the whole complex space, and satisfies

(5.13)
$$\eta(-k_1, \dots, -k_r; -m_1, \dots, -m_r) = \mathbb{B}_{m_1, \dots, m_r}^{(-k_1, \dots, -k_r)} \quad (m_1, \dots, m_r \in \mathbb{Z}_{\geq 0}).$$

Proof. As in the proof of Theorem 2.3, let

$$(5.14) H(-k_{1}, \dots, -k_{r}; s_{1}, \dots, s_{r})$$

$$= \int_{\mathcal{C}^{r}} \prod_{j=1}^{r} t_{j}^{s_{j}-1} \frac{\operatorname{Li}_{-k_{1}, \dots, -k_{r}}^{\mathsf{u}} (1 - e^{\sum_{\nu=1}^{r} t_{\nu}}, \dots, 1 - e^{t_{r}})}{\prod_{j=1}^{r} (1 - e^{\sum_{\nu=j}^{r} t_{\nu}})} \prod_{j=1}^{r} dt_{j}$$

$$= \prod_{j=1}^{r} (e^{2\pi i s_{j}} - 1) \int_{\varepsilon}^{\infty} \dots \int_{\varepsilon}^{\infty} \prod_{j=1}^{r} t_{j}^{s_{j}-1} \frac{\operatorname{Li}_{-k_{1}, \dots, -k_{r}}^{\mathsf{u}} (1 - e^{\sum_{\nu=1}^{r} t_{\nu}}, \dots, 1 - e^{t_{r}})}{\prod_{j=1}^{r} (1 - e^{\sum_{\nu=j}^{r} t_{\nu}})} \prod_{j=1}^{r} dt_{j}$$

$$+ \int_{C_{\varepsilon}^{r}} \prod_{j=1}^{r} t_{j}^{s_{j}-1} \frac{\operatorname{Li}_{-k_{1}, \dots, -k_{r}}^{\mathsf{u}} (1 - e^{\sum_{\nu=1}^{r} t_{\nu}}, \dots, 1 - e^{t_{r}})}{\prod_{j=1}^{r} (1 - e^{\sum_{\nu=j}^{r} t_{\nu}})} \prod_{j=1}^{r} dt_{j},$$

where \mathbb{C}^r is the direct product of the contour \mathbb{C} defined before. Note that the integrand on the second member has no singularity on \mathbb{C}^r . It follows from Lemma 5.5 that $H(-k_1, \ldots, -k_r; s_1, \ldots, s_r)$ is absolutely convergent for any $(s_j) \in \mathbb{C}^r$, namely is entire. Suppose $\text{Re}(s_j) > 0$ for each j, the second integral tends to 0 as $\varepsilon \to 0$. Hence

$$\eta(-k_1,\ldots,-k_r;s_1,\ldots,s_r) = \frac{1}{\prod_{i=1}^r (e^{2\pi i s_i} - 1)\Gamma(s_i)} H(-k_1,\ldots,-k_r;s_1,\ldots,s_r),$$

which can be analytically continued to \mathbb{C}^r . Also, setting $(s_1, \ldots, s_r) = (-m_1, \ldots, -m_r) \in \mathbb{Z}^r_{\leq 0}$ in (5.14), we obtain (5.13) from (5.4). This completes the proof.

Next we directly construct the generating function of $\eta(-k_1, \ldots, -k_r; s_1, \ldots, s_r)$. We prepare the following two lemmas which we consider when (x_i) is in Λ_r defined by (5.5).

Lemma 5.8. For $(s_j) \in \mathbb{C}^r$ with $\operatorname{Re}(s_j) > 0 \ (1 \le j \le r)$,

(5.15)
$$F(x_1, \dots, x_r; s_1, \dots, s_r; r) = \frac{1}{\prod_{j=1}^r \Gamma(s_j)} \int_0^\infty \dots \int_0^\infty \prod_{j=1}^r \left\{ t_j^{s_j - 1} \frac{e^{\sum_{\nu=j}^r x_\nu}}{1 - e^{\sum_{\nu=j}^r x_\nu} (1 - e^{\sum_{\nu=j}^r t_\nu})} \right\} \prod_{j=1}^r dt_j.$$

Proof. Substituting $n^{-s} = (1/\Gamma(s)) \int_0^\infty t^{s-1} e^{-nt} dt$ into the second member of (5.4), we have

$$F(\lbrace x_{j}\rbrace; \lbrace s_{j}\rbrace; r) = \sum_{l_{1}, \dots, l_{r}=1}^{\infty} \prod_{j=1}^{r} \left(1 - e^{-\sum_{\nu=j}^{r} x_{\nu}}\right)^{l_{j}-1} \frac{1}{\prod_{j=1}^{r} \Gamma(s_{j})} \times \int_{0}^{\infty} \dots \int_{0}^{\infty} \prod_{j=1}^{r} \left\{ t_{j}^{s_{j}-1} \exp\left(-(\sum_{\nu=1}^{j} l_{\nu})t_{j}\right) \right\} \prod_{j=1}^{r} dt_{j}.$$

We see that the integrand on the right-hand side can be rewritten as

$$\prod_{j=1}^r t_j^{s_j-1} \prod_{j=1}^r \exp\left(-l_j(\sum_{\nu=j}^r t_\nu)\right).$$

Hence we have

$$F(\lbrace x_{j}\rbrace;\lbrace s_{j}\rbrace;r) = \frac{1}{\prod_{j=1}^{r}\Gamma(s_{j})\left(1 - e^{-\sum_{\nu=j}^{r}x_{\nu}}\right)} \int_{0}^{\infty} \cdots \int_{0}^{\infty} \prod_{j=1}^{r} t_{j}^{s_{j}-1} \times \sum_{l_{1},\dots,l_{r}=1}^{\infty} \prod_{j=1}^{r} \left(1 - e^{-\sum_{\nu=j}^{r}x_{\nu}}\right)^{l_{j}} e^{-l_{j}(\sum_{\nu=j}^{r}t_{\nu})} \prod_{j=1}^{r} dt_{j}$$

$$= \frac{1}{\prod_{j=1}^{r}\Gamma(s_{j})} \int_{0}^{\infty} \cdots \int_{0}^{\infty} \prod_{j=1}^{r} t_{j}^{s_{j}-1} \frac{e^{-\sum_{\nu=j}^{r}t_{\nu}}}{1 - \left(1 - e^{-\sum_{\nu=j}^{r}x_{\nu}}\right) e^{-\sum_{\nu=j}^{r}t_{\nu}}} \prod_{j=1}^{r} dt_{j}$$

$$= \frac{1}{\prod_{j=1}^{r}\Gamma(s_{j})} \int_{0}^{\infty} \cdots \int_{0}^{\infty} \prod_{j=1}^{r} t_{j}^{s_{j}-1} \frac{e^{\sum_{\nu=j}^{r}x_{\nu}}}{1 - e^{\sum_{\nu=j}^{r}x_{\nu}} \left(1 - e^{\sum_{\nu=j}^{r}t_{\nu}}\right)} \prod_{j=1}^{r} dt_{j}.$$

This completes the proof.

Lemma 5.9. Let $z_1, \ldots, z_r \in \mathbb{C}$ and assume that $|z_j|$ $(1 \le j \le r)$ are sufficiently small. Then

(5.16)
$$\prod_{j=1}^{r} \frac{z_{j} e^{\sum_{\nu=j}^{r} x_{\nu}}}{1 - z_{j} e^{\sum_{\nu=j}^{r} x_{\nu}}} = \sum_{k_{n}=0}^{\infty} \operatorname{Li}_{-k_{1}, \dots, -k_{r}}^{\mathbf{u}}(z_{1}, \dots, z_{r}) \frac{x_{1}^{k_{1}} \cdots x_{r}^{k_{r}}}{k_{1}! \cdots k_{r}!}.$$

Set $z_j = 1 - e^{\sum_{\nu=j}^r t_{\nu}} \ (1 \le j \le r) \ for \ (t_j) \in \Lambda_r$. Then

(5.17)
$$\prod_{j=1}^{r} \frac{e^{\sum_{\nu=j}^{r} x_{\nu}} \left(1 - e^{\sum_{\nu=j}^{r} t_{\nu}}\right)}{1 - e^{\sum_{\nu=j}^{r} x_{\nu}} \left(1 - e^{\sum_{\nu=j}^{r} t_{\nu}}\right)}$$

$$= \sum_{k_{1}, \dots, k_{n}=0}^{\infty} \operatorname{Li}_{-k_{1}, \dots, -k_{r}}^{\mathbf{u}} \left(1 - e^{\sum_{\nu=1}^{r} t_{\nu}}, \dots, 1 - e^{t_{r}}\right) \frac{x_{1}^{k_{1}} \cdots x_{r}^{k_{r}}}{k_{1}! \cdots k_{r}!}.$$

In particular, the case $t_1 = \cdots = t_{r-1} = 0$ and $t_r = t$ implies (4.13).

Proof. We have only to prove (5.16). Actually we have

$$\sum_{k_1,\dots,k_r=0}^{\infty} \operatorname{Li}_{-k_1,\dots,-k_r}^{\mathbf{m}}(z_1,\dots,z_r) \frac{x_1^{k_1} \cdots x_r^{k_r}}{k_1! \cdots k_r!}$$

$$= \sum_{k_1,\dots,k_r=0}^{\infty} \sum_{m_1,\dots,m_r=1}^{\infty} \prod_{j=1}^{r} \frac{((\sum_{\mu=1}^{j} m_{\mu}) x_j)^{k_j}}{k_j!} z^{m_j}$$

$$= \sum_{m_1,\dots,m_r=1}^{\infty} \prod_{j=1}^{r} z_j^{m_j} \prod_{\mu=1}^{j} e^{m_{\mu} x_j}$$

$$= \sum_{m_1,\dots,m_r=1}^{\infty} \prod_{j=1}^{r} \left(z_j e^{\sum_{\nu=j}^{r} x_{\nu}} \right)^{m_j} = \prod_{j=1}^{r} \frac{z_j e^{\sum_{\nu=j}^{r} x_{\nu}}}{1 - z_j e^{\sum_{\nu=j}^{r} x_{\nu}}}.$$

Thus we have the assertion.

Using these lemmas, we obtain the following.

Theorem 5.10. For $k_1, ..., k_r \in \mathbb{Z}_{>0}$,

(5.18)
$$\eta(-k_1, \dots, -k_r; s_1, \dots, s_r) = \mathbb{B}_{k_1, \dots, k_r}^{(s_1, \dots, s_r)}.$$

Proof. By Lemmas 5.8 and 5.9, we have

(5.19)
$$F(x_{1},...,x_{r};s_{1},...,s_{r};r)$$

$$= \frac{1}{\prod_{j=1}^{r} \Gamma(s_{j})} \int_{0}^{\infty} \cdots \int_{0}^{\infty} \prod_{j=1}^{r} \left\{ t_{j}^{s_{j}-1} \frac{e^{\sum_{\nu=j}^{r} x_{\nu}}}{1 - e^{\sum_{\nu=j}^{r} x_{\nu}} (1 - e^{\sum_{\nu=j}^{r} t_{\nu}})} \right\} \prod_{j=1}^{r} dt_{j}$$

$$= \frac{1}{\prod_{j=1}^{r} \Gamma(s_{j})} \sum_{k_{1},...,k_{r}=0}^{\infty} \left\{ \int_{0}^{\infty} \cdots \int_{0}^{\infty} \prod_{j=1}^{r} t_{j}^{s_{j}-1} \times \frac{\operatorname{Li}_{-k_{1},...,-k_{r}}^{\mathbf{u}} (1 - e^{\sum_{\nu=1}^{r} t_{\nu}}, \ldots, 1 - e^{t_{r}})}{\prod_{j=1}^{r} (1 - e^{\sum_{\nu=j}^{r} t_{\nu}})} \prod_{j=1}^{r} dt_{j} \right\} \frac{x_{1}^{k_{1}} \cdots x_{r}^{k_{r}}}{k_{1}! \cdots k_{r}!}$$

for $\operatorname{Re}(s_j) > 0$ $(1 \le j \le r)$. Combining (5.4), (5.12) and (5.19), we obtain (5.18) for $\operatorname{Re}(s_j) > 0$ $(1 \le j \le r)$, hence for all $(s_j) \in \mathbb{C}$, because both sides of (5.18) are entire functions (see Remark 5.3).

Proof of Theorem 5.4. Setting $(s_1, \ldots, s_r) = (-m_1, \ldots, -m_r)$ in (5.18), we obtain (5.6) from (5.13). This completes the proof of Theorem 5.4.

Example 5.11. We can easily see that

$$\operatorname{Li}_{-1,0}^{\mathsf{u}}(z_1, z_2) = \frac{z_1 z_2}{(1 - z_1)^2 (1 - z_2)}, \quad \operatorname{Li}_{0,-1}^{\mathsf{u}}(z_1, z_2) = \frac{z_1 z_2 (2 - z_1 - z_2)}{(1 - z_1)^2 (1 - z_2)^2}.$$

Hence we have

$$\mathbb{B}_{m,n}^{(-1,0)} = 2^m 3^n, \quad \mathbb{B}_{m,n}^{(0,-1)} = (2^m + 1)3^n \quad (m, n \in \mathbb{Z}_{\geq 0}).$$

Therefore $\mathbb{B}_{0,1}^{(-1,0)} = \mathbb{B}_{1,0}^{(0,-1)} = 3$. Similarly we obtain, for example,

$$\mathbb{B}_{1,0}^{(-1,-2)} = \mathbb{B}_{1,2}^{(-1,0)} = 18, \ \mathbb{B}_{1,2}^{(-3,-1)} = \mathbb{B}_{3,1}^{(-1,-2)} = 1820, \ \mathbb{B}_{2,2}^{(-2,-1)} = \mathbb{B}_{2,1}^{(-2,-2)} = 1958.$$

Remark 5.12. Hamahata and Masubuchi [14, Corollary 10] showed the special case of (5.6), namely

$$\mathbb{B}_{0,\dots,0,m}^{(0,\dots,0,-k)} = \mathbb{B}_{0,\dots,0,k}^{(0,\dots,0,-m)} \quad (m,k \in \mathbb{Z}_{\geq 0})$$

(see Remark 5.2). On the other hand, Theorem 4.7 corresponds to the case $d=1 \neq r$ except for r=1 (see Remark 5.2), hence is located in the outside of Theorem 5.4. Therefore, in (4.12), another type of multi-poly-Bernoulli numbers appear.
